[MS-NFPB]: Near Field Proximity: Bidirectional Services Protocol

Intellectual Property Rights Notice for Open Specifications Documentation

- Technical Documentation. Microsoft publishes Open Specifications documentation for protocols, file formats, languages, standards as well as overviews of the interaction among each of these technologies.
- **Copyrights.** This documentation is covered by Microsoft copyrights. Regardless of any other terms that are contained in the terms of use for the Microsoft website that hosts this documentation, you may make copies of it in order to develop implementations of the technologies described in the Open Specifications and may distribute portions of it in your implementations using these technologies or your documentation as necessary to properly document the implementation. You may also distribute in your implementation, with or without modification, any schema, IDL's, or code samples that are included in the Open Specifications.
- **No Trade Secrets.** Microsoft does not claim any trade secret rights in this documentation.
- Patents. Microsoft has patents that may cover your implementations of the technologies described in the Open Specifications. Neither this notice nor Microsoft's delivery of the documentation grants any licenses under those or any other Microsoft patents. However, a given Open Specification may be covered by Microsoft <u>Open Specification Promise</u> or the <u>Community Promise</u>. If you would prefer a written license, or if the technologies described in the Open Specifications are not covered by the Open Specifications Promise or Community Promise, as applicable, patent licenses are available by contacting <u>iplq@microsoft.com</u>.
- Trademarks. The names of companies and products contained in this documentation may be covered by trademarks or similar intellectual property rights. This notice does not grant any licenses under those rights. For a list of Microsoft trademarks, visit <u>www.microsoft.com/trademarks</u>.
- Fictitious Names. The example companies, organizations, products, domain names, email addresses, logos, people, places, and events depicted in this documentation are fictitious. No association with any real company, organization, product, domain name, email address, logo, person, place, or event is intended or should be inferred.

Reservation of Rights. All other rights are reserved, and this notice does not grant any rights other than specifically described above, whether by implication, estoppel, or otherwise.

Tools. The Open Specifications do not require the use of Microsoft programming tools or programming environments in order for you to develop an implementation. If you have access to Microsoft programming tools and environments you are free to take advantage of them. Certain Open Specifications are intended for use in conjunction with publicly available standard specifications and network programming art, and assumes that the reader either is familiar with the aforementioned material or has immediate access to it.

1 Introduction

The Near Field Proximity: Bidirectional Services Protocol provides a way for devices such as smartphones to discover services and version information on other devices. It provides a transport-agnostic means of building up impromptu connections between peers, so it can be used on any transport system where peers can subscribe to message types and publish messages based on those types. A prototypical transport is **Near Field Communication (NFC)** [ECMA-340].

Sections 1.8, 2, and 3 of this specification are normative and can contain the terms MAY, SHOULD, MUST, MUST NOT, and SHOULD NOT as defined in RFC 2119. Sections 1.5 and 1.9 are also normative but cannot contain those terms. All other sections and examples in this specification are informative.

1.1 Glossary

The following terms are defined in [MS-GLOS]:

authentication base64 big-endian BLOB domain encryption IPv4 IPv6 kev key derivation key exchange little-endian private key public kev Transmission Control Protocol (TCP) URI UTF-8 UUID

The following terms are specific to this document:

- **ChannelID:** An 8-byte value used in message exchanges to identify the channel on which the next message is published. It is generated by using cryptographically secure pseudo-random numbers to make the chance of collision in the 64-bit address space unlikely.
- **KeepAlive timer:** A method of tracking the currency of an instance of Session Factory or OobConnector object in the abstract data model. The timer is started when an object instance is created, and it keeps track of the number of references to that instance by protocol clients. When the number of client references reaches zero, the object is deleted.
- **Media Access Control (MAC) address:** A unique hardware address that identifies each node of a network. It is used by the media access control layer of the connection.
- **Near Field Communication (NFC):** An international standard for short-range wireless, contactless connectivity that provides intuitive, simple, and safe communication between electronic devices. NFC is the technology on smartphones that makes proximity scenarios possible. For example, it allows a user to wave the smartphone over a NFC-compatible device

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

to send information without needing to touch the devices together or go through multiple steps setting up a connection.

- **network layer (L3):** The third layer in the ISO/OSI reference model that provides the ability to transfer variable length data sequences from a source host on one network to a destination host on a different network while maintaining the quality of service (QoS) requested by the transport layer.
- **pub/sub:** Refers to publication/subscription, a design model in which publishers send notification of events that are received by subscribers, which have registered for those events.
- **publication:** A message placed on the underlying transport along with a type identifier. Multiple individual publication messages may be placed on the transport with the same type identifier. Peers receive a published message if they have previously subscribed to it by type.
- **subscription:** A registration with the underlying transport to receive future messages as they are published.
- **winning peer:** A peer that has the preference to be the server in future message exchanges. This term applies to the relevant message exchange between the two peers.
- **MAY, SHOULD, MUST, SHOULD NOT, MUST NOT:** These terms (in all caps) are used as described in [RFC2119]. All statements of optional behavior use either MAY, SHOULD, or SHOULD NOT.

1.2 References

References to Microsoft Open Specifications documentation do not include a publishing year because links are to the latest version of the documents, which are updated frequently. References to other documents include a publishing year when one is available.

A reference marked "(Archived)" means that the reference document was either retired and is no longer being maintained or was replaced with a new document that provides current implementation details. We archive our documents online [Windows Protocol].

1.2.1 Normative References

We conduct frequent surveys of the normative references to assure their continued availability. If you have any issue with finding a normative reference, please contact <u>dochelp@microsoft.com</u>. We will assist you in finding the relevant information. Please check the archive site, <u>http://msdn2.microsoft.com/en-us/library/E4BD6494-06AD-4aed-9823-445E921C9624</u>, as an additional source.

1.3 Overview

Although the underlying transport for the Near Field Proximity: Bidirectional Services Protocol is undefined, the protocol models the transport as a **publication/subscription** system to exchange messages between peers. The transport is modeled with the assumption that it is either active or inactive. Typically, there is user-intent to activate the transport, but that is not required. When active, the transport transmits all local publications to peer subscribers on the other side of the transport, and it does so just once. When inactive, the transport does not transmit or receive any data.

Peers can use the information in protocol messages to activate services. A **Service Descriptor** contains a list of services and versions that are defined by this protocol. Each service is identified by a **UUID**, which peers can use to send activation messages for the service. To exchange **Service Descriptor** messages, each peer both publishes and subscribes to the service.

Some services can be inherently client/server, so that upon reception of a **Service Descriptor** message with a compatible service, a client may immediately activate this service by replying with an activation message.

Other services can be inherently peer-to-peer and use client preference ID fields to determine the specific peer that will begin the next phase of service activation. Each peer randomly generates an ID to provide highly probable uniqueness and includes the ID in each **Service Descriptor**. The peer that generates the numerically higher ID is the **winning peer**, and it sends the next message for a given service. A specific peer can only be winning or losing with respect to another specific peer.

When a client application establishes a connection over the **network layer (L3)**, it validates the connection by exchanging handshake data with the server, as described in section 1.3.4 Connection Validation.

1.3.1 Session Factory Service Activation

Either peer can choose to activate the remote peer's **Session Factory** service in order to establish a single-instanced session between an application running locally and another instance of the same application running on the remote peer. Optionally, a peer can support launching or acquiring the application in addition to, or instead of, establishing the single-instanced session between two instances of the application.

1.3.2 Oob Connector Service Activation

A winning peer can activate the remote peer's **Oob Connector** service in order to provide out-ofband transport options for the peers to connect. These connection options allow the **Session Factory** service a simple means of address resolution.

1.3.3 Session Activation

The following diagram shows a generic sequence of session activation.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

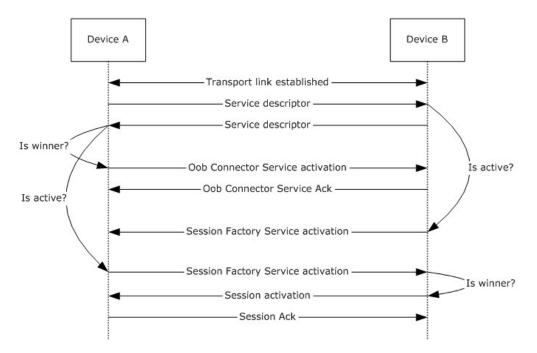

Figure 1: Session activation sequence

1.3.4 Connection Validation

After session activation (section 1.3.3) and subsequent L3 establishment, the client validates the connection by exchanging handshake data with the server, as shown in the following diagram. The handshake data consists of an Accept Header (section 2.2.1).

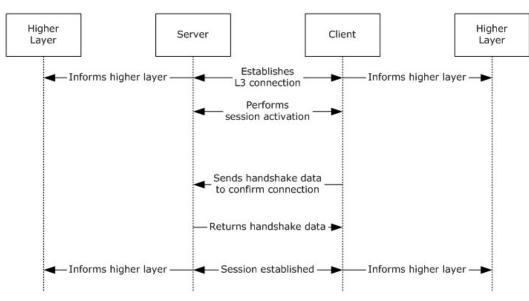

Figure 2: Connection validation

1.4 Relationship to Other Protocols

The following diagram shows the relationship of the Near Field Proximity: Bidirectional Services Protocol with other protocols.

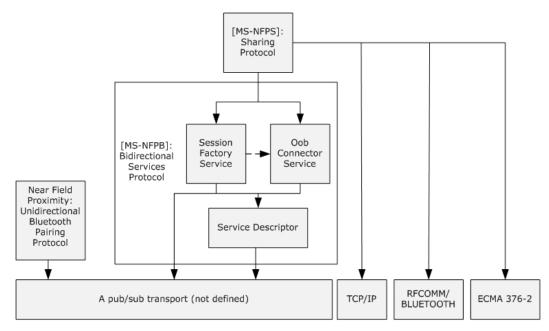

Figure 3: Relationship to other protocols

The **Service Descriptor** does not depend on any specific transport, and as such, does not technically depend on any other protocol.

The **Oob Connector** service depends only on the **Service Descriptor** for service discovery, versioning, and winner/loser role-determination. The **Oob Connector** service uses the publication/subscription transport for activation and acknowledgment. The exchanged data is combined with data exchanged by the **Session Factory** service by higher-level protocols to establish single-instanced connections between applications.

The **Session Factory** service depends only on the **Service Descriptor** for service discovery and versioning; it does not depend on the **Service Descriptor** for winner/loser role-determination. The **Session Factory** service performs winner/loser role-determination in the activation message exchange rather than the **Service Descriptor** message exchange. The **Session Factory** service uses the publication/subscription transport for winner/loser role-determination, activation, and acknowledgement. As described previously, the exchanged data in activation and acknowledgment scenarios is combined with data exchanged by the **Oob Connector** service by higher-level protocols to establish single-instanced connections between applications. These connections are typically established over **TCP**/IP or RFCOMM/Bluetooth. However, the **Oob Connector** service does not mandate a specific transport. The higher-level protocol can determine, at runtime, which transports to use to establish the session's connection.

The Near Field Proximity: Sharing Protocol [MS-NFPS] is an example of a higher-level protocol.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

1.5 Prerequisites/Preconditions

Peers must be able to communicate by using compatible networking technologies such as TCP/IP over wireless networks. There are no other preconditions or prerequisites for this protocol to function between peers. There are no presupposed security associations or connections required between peers except those that are required by the unspecified **pub/sub** transport link layer.

1.6 Applicability Statement

The Near Field Proximity: Bidirectional Services Protocol is well-suited to function on top of transports such as Near Field Communication (NFC) [ECMA-340]. This protocol has been designed for linking two applications for the purposes of simple real-time sharing of files. This protocol is designed to function in cross-platform, cross-**domain**, and non-domain configurations.

1.7 Versioning and Capability Negotiation

This document covers versioning issues in the following areas:

- Security and Authentication Methods: The Service Descriptor neither requires nor provides any security or authentication methods. The Oob Connector service and Session Factory service contain specific embedded key exchange algorithms that can be used by higher-level protocols to provide a level of security for continuing communication over an out-of-band channel. However, the specific algorithms are attached to specific versions of the Session Factory service; there is not a more granular means of negotiating algorithms.
- **Capability Negotiation:** This protocol performs explicit capability negotiation by using the **Service Descriptor** structure (section <u>2.2.9</u>).

1.8 Vendor-Extensible Fields

1.8.1 Service Descriptor Entries

Each entry within a **Service Descriptor** message (section 2.2.8) is a **Service Descriptor** structure (section 2.2.9), which contains a service activation UUID that uniquely identifies each service. Vendors that wish to define a new service MUST generate a new UUID for the service.

1.8.2 AppInfo Platform Qualifiers

AppInfo platform qualifiers SHOULD be defined by each vendor that implements any of the following protocols:

- The Session Factory protocol
- The Launch App protocol
- The Launch Compatible App protocol

A vendor SHOULD define its qualifier based on a domain name, like "fabrikam.com", which is owned by the vendor, to ensure that no other vendor uses the same value. The platform qualifier is specified by an **AppInfo** structure (section <u>2.2.2</u>).

1.8.3 Session Activation and Acknowledgment Extensions

The Session Factory protocol has an extension pattern that can be used by implementations of this protocol. If an implementation defines an extension, a random 8-byte value SHOULD be used to

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

ensure that no other implementation uses the same value. 8 bytes is usually enough to make collisions unlikely.

1.9 Standards Assignments

None.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

2 Messages

2.1 Transport

As stated earlier in this document, a specific transport is not defined. However, the general requirements for a transport are as follows:

Transports on which this protocol is built MUST be able to provide reliable packet-based delivery of messages. The transport MUST be able to provide the size of each message, independently of its payload, to the component that implements the protocol.

Messages are published and subscribed over the transport on channels that are analogous to ports in TCP/IP. Well-known channel names allow two peers to establish initial communication. If a bidirectional exchange is required, the first message SHOULD contain an ID that allows the receiver to return a message on a channel based on that ID.

In this document, all multi-message exchanges except the final message use an 8-byte identifier to denote the channel on which the following message MUST be published. This identifier is referred to as a **ChannelID**. ChannelIDs MUST be generated by using cryptographically secure pseudo-random numbers to reduce the likelihood of collisions. A collision can result in a protocol failure, which means that the exchange MUST be manually attempted again. With NFC as the typical transport, the user is required to tap or swipe the devices together again. However, with 64 bits of ChannelID address space, the chance of collision is unlikely.

Some transports, like NFC, require that the channel be encoded in characters that are allowed in a **URI**. When that is the case, the channel MUST be encoded by using **base64** [RFC2045], with the exception that padding characters MUST be omitted. ChannelIDs that are 8 bytes therefore result in channels that are exactly 11 characters long.

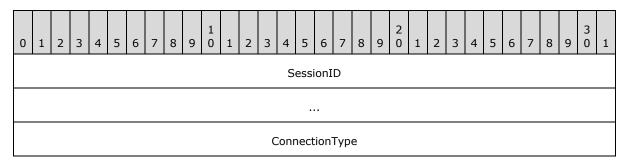

2.2 Message Syntax

None of the messages in this protocol has alignment requirements; that is, there are no padding bytes for forcing specific alignment. Additionally, fields are made as small as possible to optimize for fast transmission over low-bit-rate transports. Unless explicitly specified otherwise, all fields use **big-endian** encoding.

There is no single common header for all messages in this protocol; however, there are some common structures within messages, which are described in the sections that follow.

2.2.1 Accept Header

The **Accept** header is sent by a client application to the server after a session is activated over an L3 connection. The server MUST validate the handshake data and return the same **Accept** header to the client on the connected socket.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- SessionID (8 bytes): This MUST be the same value that the client generated and sent in the ReplyChannelID field of the preceding Session Activation message (section 2.2.11). The SessionID verification ensures that the applications that tapped are the ones that are connected over L3.
- **ConnectionType (4 bytes):** Indicates the type of transport that the server and client connected over. This MUST be set to one of the following values:

Value	Connection Type
0×0000000	Wi-Fi Direct (WFD)
0x0000001	Link Local (IPv6)
0x0000002	Link Local (IPv4)
0x0000004	Bluetooth

2.2.2 AppInfo Structure

The **AppInfo** structure is used by platforms implementing the Session Factory protocol, the Launch App protocol, or the Launch Compatible App protocol. The **AppInfo** structure format is specified as follows.

0	1	2	3	4	5	6	7	8	9	1 0	1	2	3	4	5	6	7	8	9	2 0	1	2	3	4	5	6	7	8	9	3 0	1
	Plat	forr	nQı	ualif	fiers	Size	9									Pla	tfor	mQ	uali	fier	(va	riat	ole)								
		A	opI	DSiz	ze												А	ppI	י) D	vari	able	e)									

- **PlatformQualifierSize (1 byte):** The length of the **PlatformQualifier** field, in bytes. The value MUST be greater than zero and less than or equal to 20.
- **PlatformQualifier (variable):** A **UTF-8** string that specifies the namespace for the application identifier **AppID**. This usually refers to an application store or application environment within an OS platform. The string MUST NOT be null-terminated or contain embedded nulls.

AppIDSize (1 byte): The length of the AppID field, in bytes. The value MUST be nonzero.

AppID (variable): A platform-dependent identifier for a specific application. Platforms SHOULD use the smallest identifier size that is practical in order to produce compact designs. This field contains arbitrary binary data up to the length specified in the **AppIDSize** field.

A message containing an **AppInfo** structure that does not meet any of the preceding field criteria MUST be ignored.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

2.2.3 Extension Structure

The **Extension** structure can be used by platforms implementing the Session Factory protocol. The **Extension** structure format is specified as follows:

0	1	2	3	4	5	6	7	8	9	1 0	1	2	3	4	5	6	7	8	9	2 0	1	2	3	4	5	6	7	8	9	3 0	1
													I	Exte	ensi	onT	уре	9													
	Ex	ten	sion	Dat	taSi	ze										E>	kten	isior	nDa	ta (vari	iabl	e)								
								-								•															

- **ExtensionType (8 bytes):** A platform-dependent value that identifies the type of the extension. A platform that defines an extension SHOULD declare and publish a random number to identify that extension.
- **ExtensionDataSize (1 byte):** The length of the Extension Data field in bytes. The value MUST be nonzero. Extensions not meeting this criterion MUST be ignored.
- **ExtensionData (variable):** A platform-dependent **BLOB** of data for a specific extension. Platforms SHOULD use the smallest data size that is practical in order to produce compact designs. This field contains arbitrary binary data up to the length specified in the **ExtensionDataSize** field.

2.2.4 Oob Connector Service ACK Message

The **Oob Connector Service ACK** message is the acknowledgment reply to the **Oob Connector Service Activation** message (section 2.2.5). The **Oob Connector Service ACK** message format is specified as follows:

0	1	2	3	4	5	6	7	8	9	1 0	1	2	3	4	5	6	7	8	9	2 0	1	2	3	4	5	6	7	8	9	3 0	1
	•						•		•		١	NiFi	Dire	ectA	ddr	ess	(16	5 by	tes)											
												Link	Loc	alA	ddro	ess	(16	by	tes))											

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

IPv4LinkLocalAd	IPv4LinkLocalAddress (16 bytes)								
ProximityAddr	ess (16 bytes)								
GlobalAddre	ss (16 bytes)								
	ss (16 bytes)								
	IACAddress								
	WiFiDiwatCownactDlab (variable actional)								
WiFiDirectConnectBlobLength	WiFiDirectConnectBlob (variable, optional)								

WiFiDirectAddress (16 bytes): A randomly-generated **IPv6** link-local address. If the Oob Connector protocol results in a new Wi-Fi Direct layer 2 link, the publisher MUST assign this address to the link in order to allow layer 3 connectivity.

Use of this value is optional. It SHOULD be set to zero if not used.

LinkLocalAddress (16 bytes): The best link-local IPv6 address assigned to the publisher. "Best" is defined in order of decreasing precedence of the following: connectivity, Wi-Fi infrastructure links, transmit bit rate, receive bit rate, and non-tunnel links. If no link-local address is suitable, the value of this field SHOULD be zero.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

IPv4LinkLocalAddress (16 bytes): The best **IPv4** link-local address assigned to the publisher in V4-MAPPED format. "Best" is defined in order of decreasing precedence of the following: connectivity, Wi-Fi infrastructure links, transmit bit rate, receive bit rate, and non-tunnel links. If no IPv4 link-local address is suitable, the value of this field SHOULD be zero.

This value provides for connectivity over networks that do not support link-local IPv6 traffic, such as some legacy Wi-Fi networks.

- **ProximityAddress (16 bytes):** An IPv6 address assigned to the transport link that this message is published on. Not all pub/sub transports support IP connectivity; an example that can support IP is TransferJet. If the underlying transport does not support IP, the value of this field SHOULD be zero.
- **GlobalAddress (16 bytes):** The "best" global IPv6 address assigned to the publisher. "Best" is defined in order of decreasing precedence of the following: connectivity, non-Teredo-type [RFC4380], transmit bit rate, receive bit rate, and, non-tunnel links. If no global address is suitable, the value of this field SHOULD be zero.
- **TeredoAddress (16 bytes):** The"best" Teredo-type IPv6 address assigned to the publisher. "Best" is defined in order of decreasing precedence of the following: connectivity, Teredo-type, transmit bitrate, and receive bitrate. If no Teredo address is suitable, the value of this field SHOULD be zero.

The Teredo Tunneling protocol is a technology that allows Internet nodes to have global IPv6 addressing capability tunneled over IPv4 networks.

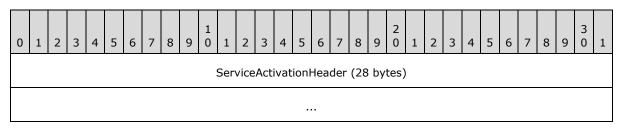

- **BlueToothMACAddress (8 bytes):** The **Media Access Control (MAC) address** of the best Bluetooth adapter available to the publisher. "Best" is defined by the platform; many platforms only allow zero or one Bluetooth adapter. If no Bluetooth adapter is available, the value of this field SHOULD be zero.
- WiFiDirectConnectBlobLength (2 bytes): The length, in bytes, of the WiFiDirectConnectBlob field that follows. If the value of this field is zero, the WiFiDirectConnectBlob field is not present.

WiFiDirectConnectBlob (variable, optional): A field that is set to an arbitrary value.

2.2.5 Oob Connector Service Activation Message

The **Oob Connector Service Activation** message is a reply to the **Service Descriptor** message (section 2.2.8). It is used to establish a paired set of **Oob Connector** objects (section 3.1.1.2) between two peers. If the local **SourceID** is greater than the **ActivationChannelID** in the received **Service Descriptor** message, an **Oob Connector Service Activation** message MUST be published on the **ReplyChannelID** of the **Session Activation** message (section 2.2.11), unless the **Oob Connector** object for that remote service is already created and active.

The Oob Connector Service Activation message format is specified as follows:

Release: Monday, July 22, 2013

17 / 57

TeredoAddress (16 bytes)							
Rese	erved						
BlueToothN	IACAddress						
WiFiDirectConnectBlobLength	WiFiDirectConnectBlob (variable, optional)						

- ServiceActivationHeader (28 bytes): A Service Activation header (section 2.2.7). The ServiceActivationUUID MUST be {E46EDA50-9B5D-41F1-B89E-327B5EA38B16}. The ServiceVersion MUST be 1.
- **ReplyChannelID (8 bytes):** This value is also the identifier of the **Oob Connector** object (section <u>3.1.1.2</u>). It MUST be generated at random by the publisher. The publisher of this message MUST subscribe to the **ReplyChannelID** prior to publishing this message to ensure that replies are not missed.
- **WiFiDirectAddress (16 bytes):** A randomly generated IPv6 link-local address. If the Oob Connector protocol results in a new Wi-Fi Direct layer 2 link, the publisher MUST assign this address to the link in order to allow layer 3 connectivity.

Use of this field is OPTIONAL. It MAY be ignored and the value SHOULD be set to zero if unused.

- **LinkLocalAddress (16 bytes):** The best link-local IPv6 address assigned to the publisher. "Best" is defined in order of decreasing precedence of the following: connectivity, Wi-Fi infrastructure links, transmit bit rate, receive bit rate, and non-tunnel links. If no link-local address is suitable, the value of this field SHOULD be zero.
- **IPv4LinkLocalAddress (16 bytes):** The best IPv4 link-local address assigned to the publisher in V4-mapped format. "Best" is defined in order of decreasing precedence of the following: connectivity, Wi-Fi infrastructure links, transmit bit rate, receive bit rate, and non-tunnel links. If no IPv4 link-local address is suitable, the value of this field SHOULD be zero.

This value provides for connectivity over networks that do not support link-local IPv6 traffic, such as some legacy Wi-Fi networks.

ProximityAddress (16 bytes): The IPv6 address assigned to the transport link that this message is published on. Not all pub/sub transports support IP connectivity; an example that can support IP is TransferJet. If the underlying transport does not support IP, the value of this field SHOULD be zero.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- **GlobalAddress (16 bytes):** The best global IPv6 address assigned to the publisher. "Best" is defined in order of decreasing precedence of the following: connectivity, non-Teredo-type [RFC4380], transmit bit rate, receive bit rate, and non-tunnel links. If no global address is suitable, the value of this field SHOULD be zero.
- **TeredoAddress (16 bytes):** The best Teredo-type IPv6 address assigned to the publisher. "Best" is defined in order of decreasing precedence of the following: connectivity, Teredo-type, transmit bit rate, and receive bit rate. If no Teredo address is suitable, the value of this field SHOULD be zero.

The Teredo Tunneling protocol is a technology that allows Internet nodes to have global IPv6 addressing capability tunneled over IPv4 networks.

- **Reserved (4 bytes):** This field MUST be set to zero when sent and MUST be ignored when received.
- **BlueToothMACAddress (8 bytes):** The Media Access Control (MAC) address of the best Bluetooth adapter available to the publisher. "Best" is defined by the platform; many platforms only allow zero or one Bluetooth adapter. If no Bluetooth adapter is available, the value of this field SHOULD be zero.
- WiFiDirectConnectBlobLength (2 bytes): The length, in bytes, of the WiFiDirectConnectBlob field that follows. If the value of this field is zero, the WiFiDirectConnectBlob field is not present.

WiFiDirectConnectBlob (variable, optional): A field that is set to an arbitrary value.

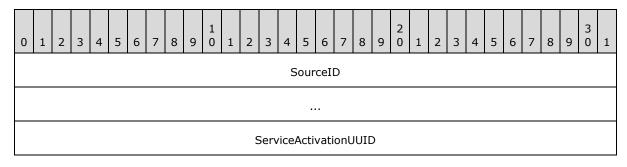

2.2.6 Role Compatibility Constants

The **Role Compatibility** constants SHOULD $\leq 1>$ be used to check the value of the **Role** field in a **Session Factory Service Activation** message (section 2.2.12) for compatibility with the role of the receiver of that message.

Value in Role field	Compatible role value
0x01 (peer role)	0x01 (peer role)
0x02 (host role)	0x03 (client role)
0x03 (client role)	0x02 (host role)

2.2.7 Service Activation Header

The **Service Activation** header is common to all service activation messages. The **Service Activation** header format is specified as follows:

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

ExtendedInfo	ServiceVersion

SourceID (8 bytes): The identifier of the system that published the activation message. The value of the **SourceID** field MUST be identical to the value of the **ActivationChannelID** field that the sending system also published within its **Service Descriptor** message (section 2.2.8). This identifier is not used as the reply ChannelID for this message; it is used for debugging and role determination. If the activation message requires a reply message, the reply ChannelID MUST be specified in the body of the specific activation message rather than in this header.

ServiceActivationUUID (16 bytes): A UUID that specifies the service being activated.

- **ExtendedInfo (2 bytes):** This field is primarily provided for 32-bit alignment of the **Service Activation** header. All service protocols defined in this specification require that this field SHOULD be zero; however, it can safely be ignored by receivers. Other service protocols might require other uses for this field.
- **ServiceVersion (2 bytes):** An unsigned integer that specifies the version of the service being activated. The value MUST be nonzero; service activations containing a zero service version MUST be ignored. The first version of all service protocols MUST be 1. A peer that supports version *X* of a given service MUST support activations with versions 1 through *X*.

2.2.8 Service Descriptor Message

The **Service Descriptor** message MUST be published and subscribed at the following well-known channel: "Windows.windows.com/SD".

The length of the **Service Descriptor** message MUST be provided by the transport layer in order to allow the determination of the number of **Service Descriptor (SD)** structures (section 2.2.9) contained within it. Each **SD** structure MUST be fully decoded before being accepted, and if a partial structure occurs at the end of the **Service Descriptor** message, it MUST be ignored.

0	1	2	3	4	5	6	7	8	9	1 0	1	2	3	4	5	6	7	8	9	2 0	1	2	3	4	5	6	7	8	9	3 0	1
													Act	ivat	ion	Cha	nne	elID													
	ServiceDescriptorArray (variable)																														

The **Service Descriptor** message format is specified as follows:

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

ActivationChannelID (8 bytes): The source identifier of the system that published the Service **Descriptor** message. This value SHOULD be used as the reply ChannelID by the receiver for any activation messages.

ServiceDescriptorArray (variable): Some number of **SD** structures. The **SD** structure format is specified in section <u>2.2.9</u>.

2.2.9 Service Descriptor Structure

The **Service Descriptor (SD)** structure specifies a service to be activated and provides for explicit capability negotiation. An array of **SD** structures is specified in a **Service Descriptor** message (section 2.2.8). The **SD** structure format is specified as follows:

0 1 2 3 4 5 6 7 8 9 1 1 2 3 4 5	6 7 8 9 2 1 2 3 4 5 6 7 8 9 3 1								
ServiceActivatio	nUUID (16 bytes)								
ExtendedInfo1	ServiceVersion								
ExtendedInfo2 ExtendedPayloadLength									
ExtendedPayload (variable, optional)									

ServiceActivationUUID (16 bytes): The UUID of the specific service being activated.

- **ExtendedInfo1 (2 bytes):** Service-specific extension information. Each service protocol SHOULD define what this field is used for.
- **ServiceVersion (2 bytes):** A positive integer that specifies the version of the service being activated. The value SHOULD be nonzero; service activations containing a zero service version MUST be ignored. The first version of all service protocols MUST be 1. A peer that claims to support version *X* of a given service MUST support activations with versions 1 through *X*.
- **ExtendedInfo2 (2 bytes):** Service-specific extension information. Each service protocol SHOULD define what this field is used for.
- **ExtendedPayloadLength (2 bytes):** The length in bytes of additional service-specific extension information in the **ExtendedPayload** field. Each service protocol SHOULD define whether or not the Extended Payload is used. If this field is nonzero, but there are not enough bytes left in this message, then this last entry is ill-formed and MUST be ignored.
- **ExtendedPayload (variable, optional):** Additional service-specific extension information. Each service protocol defines whether or not this information is used, and if so, how it is used.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

The service listed in the **SD** MUST have a positive integer **ServiceVersion** value associated with it. If an implementation specifies a service with version X in its published **SD**, the implementation MUST be compatible with all version numbers less than or equal to X. If an implementation cannot support prior versions, it MUST specify a new

ServiceActivationUUID, in effect creating a new service. A **Service Activation** header (section <u>2.2.7</u>) contains the UUID of the service to activate and the service version number.

2.2.10 Session ACK Message

The **Session ACK** message is the acknowledgment/reply to the **Session Activation** message (section 2.2.11). The transport-provided length of this message MUST be used by the receiver in order to determine the existence or number of extension structures that follow the non-optional portions of the message. The publisher MUST NOT publish messages that are less than 75 bytes long to a **Session Activation** message's **ReplyChannelID**. The subscriber MUST drop all **Session ACK** messages that are less than 75 bytes long.

The **Session ACK** message format is specified as follows:

0	1	2	3	4	5	6	7	8	9	1 0	1	2	3	4	5	6	7	8	9	2 0	1	2	3	4	5	6	7	8	9	3 0	1
ECDHPublicKeyMagicNumber																															
	ECDHPublicKeyLength																														
	ECDHXParam																														
	ECDHYParam																														
	TCPPort RFCOMMPort Reserved1 (optional)																														
													Res	erv	ed2	(op	otio	nal)													
													Res	erv	ed3	(op	otio	nal)													
	Reserved4 (optional) ExtensionCount (optional)																														
	ExtensionStructures (variable, optional)																														

ECDHPublicKeyMagicNumber (4 bytes): The 4-byte value 0x45, 0x43, 0x4B, and 0x31. This indicates that the Elliptic Curve Diffie-Hellman (ECDH) key exchange follows the P256 convention [NSA].

ECDHPublicKeyLength (4 bytes): A 32-bit, unsigned integer in **little-endian** format that specifies the **key** length in bytes. This value MUST be 0x00000020.

ECDHXParam (4 bytes): A 32-bit, unsigned integer that specifies the X coordinate of a singleuse, generated ECDH **public key**. The **private key** portion MUST NOT be transmitted and is

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

used in the local **Session** object (section 3.1.1.4) with the ECDH Public Key received from the **Session Activation** message (section 2.2.11).

- **ECDHYParam (4 bytes):** A 32-bit, unsigned integer that specifies the Y coordinate of a singleuse, generated ECDH public key. The private key portion MUST NOT be transmitted and is used in the local **Session** object with the ECDH Public Key received from the **Session Activation** message.
- **TCPPort (2 bytes):** The TCP port that the publisher's session is listening on.
- RFCOMMPort (1 byte): The RFCOMM port that the publisher's session is listening on.
- **Reserved1 (1 byte, optional):** If present, this field MUST be set to zero when sent and MUST be ignored when received.
- **Reserved2 (4 bytes, optional):** If present, this field MUST be set to zero when sent and MUST be ignored when received.
- **Reserved3 (4 bytes, optional):** If present, this field MUST be set to zero when sent and MUST be ignored when received.
- **Reserved4 (2 bytes, optional):** If present, this field MUST be set to zero when sent and MUST be ignored when received.
- **ExtensionCount (2 bytes, optional):** The number of **Extension** structures (section 2.2.3) in the **ExtensionStructures** field. Use of this field is platform specific. A subscriber MUST ignore extensions that it does not process.

If this message is between 75 and 87 bytes long (inclusive), the value of this field is treated as zero.

ExtensionStructures (variable, optional): Zero or more **Extension** structures. Any incorrectly formatted **Extension** structures MUST be ignored by the subscriber.

2.2.11 Session Activation Message

The **Session Activation** message is a reply to the **Session Factory Service Activation** message (section 2.2.12). It is used to establish a paired set of **Session** objects (section 3.1.1.4) between two peers. For each active **Session Factory** object (section 3.1.1.3) on the receiver, a **Session Activation** message MUST be published on the **Session Factory Service Activation** message's **ReplyChannelID**, unless the **Session** object is already created and active.

The transport-provided length of this message MUST be used by the receiver in order to determine the existence or number of extension structures that follow the non-optional portions of the message. The publisher MUST NOT publish messages to a **Session Factory Service Activation** message's **ReplyChannelID** that are less than 96 bytes long. The subscriber MUST drop all **Session Activation** messages that are less than 96 bytes long.

1 2 3 7 8 9 2 5 9 2 3 4 5 7 8 9 3 5 0 3 6 7 8 0 1 6 0 1 0 1 2 4 6 1 4 SourceID

The **Session Activation** message format is specified as follows:

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

Release: Monday, July 22, 2013

ECDH>	(Param							
ECDHY	'Param							
Rese	rved1							
Rese	rved2							
Reserved3 ExtensionCount								
ExtensionStructures (variable, optional)								

- SourceID (8 bytes): The publisher identification to the subscriber. The publisher of this message MUST set this field to the value of the ActivationChannelID field specified in the Service Descriptor message that is the source identifier of the publisher. This allows a created Session object for the peers to reference an Oob Connector object (section 3.1.1.2) for the same two peers.
- ActivatedSessionFactoryID (8 bytes): The identifier of the active Session Factory object that was activated by the Session Factory Service Activation message.
- **ReplyChannelID (8 bytes):** The identifier of the newly created **Session** object. It MUST be generated at random by the publisher. The publisher of this message MUST subscribe to the **ReplyChannelID** prior to publishing this message to ensure that replies are not missed. The publisher MUST handle **Session ACK** messages (section 2.2.10) on this channel.
- **ECDHPublicKeyMagicNumber (4 bytes):** The 4-byte value 0x45, 0x43, 0x4B, and 0x31. This indicates that the Elliptic Curve Diffie-Hellman (ECDH) key exchange follows the P256 convention [NSA].
- **ECDHPublicKeyLength (4 bytes):** A 32-bit, unsigned integer in little-endian format that specifies the key length in bytes. This value MUST be 0x0000020.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- **ECDHXParam (4 bytes):** A 32-bit, unsigned integer that specifies the X coordinate of a singleuse, generated ECDH public key. The private key portion MUST NOT be transmitted and is held in the local **Session** object for later use when the **Session ACK** message is received.
- **ECDHYParam (4 bytes):** A 32-bit, unsigned integer that specifies the Y coordinate of a singleuse, generated ECDH public key. The private key portion MUST NOT be transmitted and is held in the local **Session** object for later use when the **Session ACK** message is received.
- **Reserved1 (4 bytes):** This field MUST be set to zero when sent and MUST be ignored when received.
- **Reserved2 (4 bytes):** This field MUST be set to zero when sent and MUST be ignored when received.
- **Reserved3 (2 bytes):** This field MUST be set to zero when sent and MUST be ignored when received.
- **ExtensionCount (2 bytes):** The number of **Extension** structures (section 2.2.3) in the **ExtensionStructures** field. Use of this field is platform-specific. A subscriber MUST ignore extensions that it does not process.

If this message is between 96 and 107 bytes long (inclusive), the value of this field is treated as zero.

ExtensionStructures (variable, optional): Zero or more **Extension** structures. Any incorrectly formatted **Extension** structures MUST be ignored by the subscriber.

If the **Session Factory Service Activation** message to which this **Session Activation** message is a response contains a **Role** field, the following additional requirements for this message are defined:<<2>

- The input **Role** field value SHOULD be checked, as specified in section <u>3.1.5.6</u>.
- The Extension structure in the ExtensionStructures field SHOULD be structured as follows:

ExtensionType (8 bytes): The value 0x89A14CC3AB4CF821.

ExtensionDataSize (1 byte): The value 0x01.

ExtensionData (1 byte): The compatible role value according to the **Role Compatibility** constants (section 2.2.6).

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

2.2.12 Session Factory Service Activation Message

The **Session Factory Service Activation** message is a reply to the **Service Descriptor** message (section 2.2.8). It is used to establish a paired set of **Session** objects (section 3.1.1.4) between two peers. For each active **Session Factory** object (section 3.1.1.3) on the receiver, a **Session Activation** message (section 2.2.11) MUST be published on the **ReplyChannelID** of the **Session Factory Service Activation** message, unless the **Session** object is already created and active.

2 3 1 0 1 2 3 4 5 6 7 8 9 0 2 3 4 5 6 7 8 9 0 1 2 3 5 7 8 9 0 1 1 4 6 ServiceActivationHeader (28 bytes) ... (continued for 5 additional rows) ReplyChannelID ... ClientPreference Reserved1 L Reserved2 AppInfoStructures (variable) AppInfoCount Role (optional) . . .

The Session Factory Service Activation message format is specified as follows:

ServiceActivationHeader (28 bytes): A Service Activation header (section 2.2.7). The ServiceActivationUUID value SHOULD<3> be {F1DEBC56-CFBA-4129-983B-7D79499D1A7D} for a peer role or {DAA42D35-1323-485A-8B34-3B86E416E6EC} for a host or client role. If it is the latter, the **Role** field MUST be included in this message, as specified later in this section.

The ServiceVersion value in the Service Activation header MUST be 1.

- **ReplyChannelID (8 bytes):** This value is also the identifier of the **SessionFactory** object (section <u>3.1.1.3</u>). It MUST be generated at random by the publisher. The publisher of this message MUST subscribe to the **ReplyChannelID** prior to publishing this message to ensure that replies are not missed. The publisher MUST handle **Session Activation** messages on this channel.
- **ClientPreference (4 bytes):** The preference of the sender to be the peer that actually sends the subsequent **Session Activation** message. Values higher than 0x1000 indicate a preference to have **Session** objects be the client role. Values lower than 0x1000 indicate a preference to have **Session** objects be the server role.
- **Reserved1 (7 bits):** This field MUST be set to zero by publishers and MUST be ignored by subscribers.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- L (1 bit): The Launch flag. The presence of this flag indicates the publisher's intent for the application on the subscriber side to be launched or activated if it is not already. If this flag is not set, the subscriber MUST NOT trigger the launching of the application specified in the AppInfo structure (section 2.2.2).
- **Reserved2 (3 bytes):** This field MUST be set to zero by publishers and MUST be ignored by subscribers.
- AppInfoCount (1 byte): The number of AppInfo structures that follow this field. The publisher MUST provide 1 or more AppInfo structures. If this field is zero, the entire message MUST be ignored by the subscriber.
- **AppInfoStructures (variable):** An array of **AppInfo** structures. Typically the first one uniquely refers to the application on the platform that published this message. The publisher can provide application information that refers to the application on other platforms for the purposes of interoperation.
- **Role (1 byte, optional):** The session role of the application. This field SHOULD<4> be included in this message if the application role is either host or client. The following values are valid:

Value	Description
0x02	Host role
0x03	Client role

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

3 Protocol Details

3.1 Peer Details

This section defines peer roles in the Near Field Proximity: Bidirectional Services Protocol.

In a socket-based connection between two peer applications, one peer has the role of client, and the other peer has the role of server. The roles are distinguished as follows:

 The client is the peer that sends the Session Activation message (section 2.2.11) and waits for the Session ACK message (section 2.2.10).

The server is the peer that receives the **Session Activation** message and sends the **Session ACK** message.

Possible states and state transitions of the client and server roles are described in section 3.1.1.4.

In an out-of-band connection between two peers, one peer has the role of connector, and the other peer has the role of listener. The roles are distinguished as follows:

- The connector is the peer that sends the **Oob Connector Service Activation** message (section 2.2.5) and waits for the **Oob Connector Service ACK** message (section 2.2.4).
- The listener is the peer that receives the **Oob Connector Service Activation** message and sends the **Oob Connector Service ACK** message.

Possible states and state transitions of the connector and listener roles are described in section 3.1.1.2.

3.1.1 Abstract Data Model

This section describes a conceptual model of possible data organization that an implementation maintains to participate in this protocol. The described organization is provided to facilitate the explanation of how the protocol behaves. This document does not mandate that implementations adhere to this model as long as their external behavior is consistent with that described in this document.

The abstract data model defines **Oob Connector** objects, **Session Factory** objects, and **Session** objects. When the underlying transport is triggered, an exchange is performed by peers that can result in new instances of these objects: each peer can create an **Oob Connector** object, one in the listener role and one in the connector role. If both sides have active **Session Factory** objects that are compatible, then each peer creates a **Session** object, one in the client role and one in the server role.

Each **Session** object references one **Oob Connector** object in order to provide connectivity options to higher-level protocols.

If there is only one peer with an active **Session Factory** object, but it specifies the **L** (Launch) flag in the **Session Factory Service Activation** message (section 2.2.12), then the other peer can create a **Session Factory** object on behalf of a soon-to-be-launched application. This provides for the ability to establish out-of-band connections at the same time as launching an application.

Note that the abstract interface notation (Public) indicates that the abstract data model element can be directly read or written from outside this protocol by higher-level protocols. For example, the

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

Near Field Proximity: Sharing Protocol [MS-NFPS] uses members of the **Session** and **Oob Connector** objects to construct a socket for the purposes of sharing file(s).

3.1.1.1 NfpService

The Near Field Proximity service **NfpService** encapsulates the entire state for the protocols described by this document.

SourceID (8 bytes): A random number that uniquely identifies the NfpService instance.

OobConnectorList: A list of active **Oob Connector** objects.

SessionFactoryList (Public): A list of active Session Factory objects.

HandshakeData: The **SessionID** and **ConnectionType** handshake data from the **Accept Header** (section <u>2.2.1</u>) that was used to confirm the connection.

3.1.1.2 Oob Connector Object

An **Oob Connector** object encapsulates the state for an out-of-band connection between two peers.

Role: The role of the **Oob Connector** object. One peer is the connector, and the other peer is the listener. The roles are distinguished as follows:

- The connector is the peer that sends the Oob Connector Service Activation message (section 2.2.5) and waits for the Oob Connector Service ACK message (section 2.2.4).
- The listener is the peer that receives the **Oob Connector Service Activation** message and sends the **Oob Connector Service ACK** message.
- **State:** The current state of the **Oob Connector** object. The meaning of the state depends on the object role; this allows an asymmetric client/server message exchange. For the connector role, the state can be one of the following.

Value	Meaning
WaitingForAck	The object has published the Oob Connector Service Activation message (section $2.2.5$) and is waiting to receive the Oob Connector Service ACK message (section $2.2.4$).
Incomplete	The Oob Connector protocol timed out. The object is still alive to facilitate object continuity across multiple taps.
Ready	The object has received the Oob Connector Service ACK message and has all the information required to facilitate communications between the two peers.

The following is a diagram that shows the state transitions for the connector role of an **Oob Connector** object:

Copyright © 2013 Microsoft Corporation.

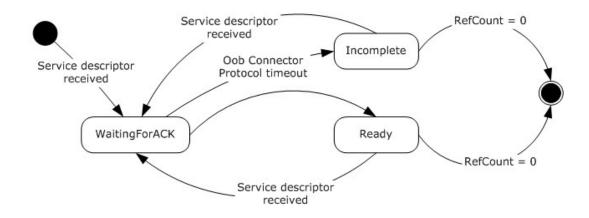

Figure 4: Oob Connector state transitions: Connector role

For the listener role, the state can be one of the following:

Value	Meaning
WaitingForTransmit	The object has received the Oob Connector Service Activation message, has published the Oob Connector Service ACK message to the transport, and is waiting for the transport to indicate the ACK message has been transmitted to a remote peer
Incomplete	The Oob Connector protocol timed out. The object is still alive to facilitate object continuity across multiple taps.
Ready	This object has received notification of successful transmission of the ACK message and has all the information required to facilitate communication between two peers.

The following is a diagram that shows the state transitions for the listener role of an **Oob Connector** object.

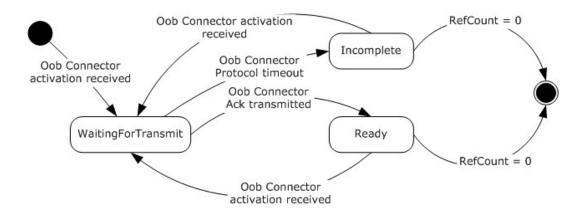

Figure 5: Oob Connector state transitions: Listener role

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- **RemoteSourceID:** This identifies the peer to which a given **Oob Connector** object is connected. For the connector, this is copied from the **ActivationChannelID** field in the received **Service Descriptor** message (section 2.2.8). For the listener, this is copied from the **SourceID** field in the **Service Activation** header (section 2.2.7) of the received **Oob Connector Service Activation** message.
- **OobConnectorID:** For the connector, this is randomly generated and used in the **Oob Connector Service Activation** message. For the listener, this is copied from the received **Oob Connector Service Activation** message.
- **WfdPeerConnected:** Boolean value that indicates whether the **Oob Connector** object has an active WFD connection to the peer.

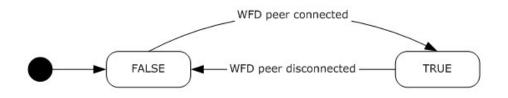

Figure 6: Oob Connector WfdPeerConnected transitions

- **LocalAddresses (Public Read):** The list of local addresses collected by the **Oob Connector** object from the local machine and sent to the remote machine via either the Activation or ACK message.
- **RemoteAddresses (Public Read):** The list of remote addresses received by the **Oob Connector** object from the remote machine via either the Activation or ACK message.
- ReferenceCount: A count of references to the **Oob Connector** object by either **Session** objects or **KeepAlive timers**.

3.1.1.3 Session Factory Object

A **Session Factory** object encapsulates a factory for socket-based connections between set(s) of peer applications.

- **SessionList:** A list of **Session** objects (section <u>3.1.1.4</u>) that are a part of this **Session Factory** object.
- AppID (Public Read/Write): A UTF-8 string that identifies the contract or interface for this Session Factory object. This Session Factory will only create and link up Session objects with other Session Factory objects that provide exactly the same AppID in the AppInfo field of the Session Factory Service Activation message (section 2.2.12).
- AlternateIDList (Public Read/Write): A list of alternate AppIDs for other platforms that the Session Factory will also attempt to activate.
- Launch (Boolean): TRUE if the L (Launch) flag SHOULD be set in the appropriate Session Factory Service Activation message. FALSE if the flag SHOULD be cleared.
- SessionFactoryID (8 bytes): A random number that uniquely identifies this instance of Session Factory object.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- **TcpPort (Public Read):** The TCP/IP Port on which the **Session Factory** is listening and can accept **Session** sockets after a **Session Activation** (section 2.2.11)/ **Session ACK** (section 2.2.10) exchange.
- **RfcommPort (Public Read):** The RFCOMM/Bluetooth Port on which the **Session Factory** is listening and can accept **Session** sockets after a **Session Activation/Session ACK** exchange.
- **ReferenceCount (Public Write):** A count of references to the **Session Factory** object by either the client application or KeepAlive timers.

3.1.1.4 Session Object

A **Session** object encapsulates the state for a socket-based connection between two peer applications.

- **Role (Public Read):** The role of the **Session** object. One peer is the client, and the other peer is the server. The roles are distinguished as follows:
 - The client is the peer that sends the Session Activation message (section 2.2.11) and waits for the Session ACK message (section 2.2.10).
 - The server is the peer that receives the **Session Activation** message and sends the **Session ACK** message.

State (Public Read/Write): The current state of the Session object. The state can be one of the following.

Value	Meaning
WaitingForAck	A client Session object transitions to this state immediately prior to publishing the Session Activation message.
WaitingForTransmit	A server Session object transitions to this state when beginning to publish the Session ACK message.
Ready	The Session object is ready to be used by an application for peer-to-peer communication. A client Session object transitions to this state after receiving the Session ACK message. A server Session object transitions to this state after successfully transmitting the Session ACK message.
Terminated	The Session object has been terminated by the application, or it timed out.

The following shows the possible state transitions for the client role of a **Session** object.

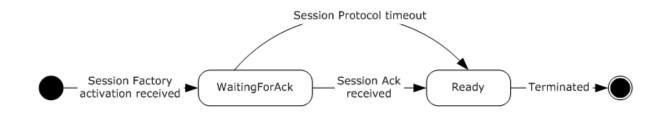

Figure 7: Session state transitions: Client role

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

The following shows the possible state transitions for the server role of a **Session** object.

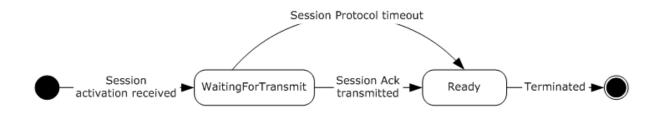

Figure 8: Session state transitions: Server role

- SessionID: For the client, this is randomly generated and used in the Session Activation message. For the server, this is copied from the **ReplyChannelID** field of the received Session Activation message. The server uses this ID to publish the Session ACK message.
- **RemoteSessionFactoryID (8 bytes):** The SessionFactoryID of the remote peer this **Session** object is connected to. For the client, this is copied from the **ReplyChannelID** field of the received **Session Factory Service Activation** message (section 2.2.12). For the server, this is copied from the **ActivatedSessionFactoryID** field of the received **Session Activation** message.
- **RemoteTcpPort (Public Read):** The TCP/IP port on which the remote **Session Factory** is listening and can accept **Session** sockets after a **Session Activation/Session ACK** exchange.
- RemoteRfcommPort (Public Read): The RFCOMM/Bluetooth port on which the remote Session Factory is listening and can accept Session sockets after a Session Activation/Session ACK exchange.
- **PrivateKey:** The private key used in an Elliptic Curve Diffie-Hellman (ECDH) exchange to derive a shared key. The client and server have different private keys and do not share them with anyone.
- **PublicKey:** The public key (linked with the **PrivateKey**) used in an Elliptic Curve Diffie-Hellman (ECDH) exchange to derive a shared key. The client and the server have different public keys and exchange them in the **Session Activation** and **Session ACK** messages.
- **SharedSecretKey (Public Read):** The key derived from the ECDH key exchange. This key is not published and SHOULD remain a shared secret between the server and clients. The key can be provided to the application on each side so that it can provide a level of authentication/**encryption** over the Session link.
- **ReferencedOobConnector:** A link to the **Oob Connector** object that holds out of band connection information for the two peers linked by the **Session** object. When present, this represents a reference count on the **Oob Connector** object.

3.1.2 Timers

The following timers are used by this protocol.

SessionProtocolTimer: An independent timer for each **Session** object (section <u>3.1.1.4</u>), which causes the **Session** object to time out if its **State** is not Ready.

The legal range for the **SessionProtocolTimer** timeout value is 8-60 seconds.<5>

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

OobConnectorProtocolTimer: An independent timer for each **Oob Connector** object, which is started each time an **Oob Connector** object **State** transitions into WaitingForTransmit or WaitingForACK. If the timer fires before the object **State** transitions to Ready, the protocol is incomplete and the object **State** transitions to Incomplete.

The legal range for the **OobConnectorProtocolTimer** timeout value is 8-60 seconds. <<u>6></u>

The following timers illustrate abstract data model object lifetime issues, but they are not necessary in all implementations:

- **OobConnectorKeepAliveTimer:** An independent timer for each **Oob Connector** object (section <u>3.1.1.2</u>), which is started each time an **Oob Connector** object **State** transitions into Incomplete. If it fires before the object **State** transitions out of Incomplete, the initialization reference SHOULD be released.
- **SessionFactoryKeepAliveTimer:** An independent timer for each **Session Factory** object (section <u>3.1.1.3</u>), which is started when a **Session Factory** object is created. If it fires before a client takes ownership of the object, the **Session Factory** object SHOULD BE deleted.<u><8></u>

3.1.3 Initialization

The **NfpService** MUST be initialized prior to being useful to any higher-level protocol; initializing at system startup is sufficient. On initialization:

- A subscription MUST be made on a Service Descriptor message (section <u>2.2.8</u>) well-known channel.
- A **SourceID** MUST be randomly generated.
- A subscription for **Session Activation** messages (section <u>2.2.11</u>) MUST be made by using the **SourceID** as the ChannelID.
- A local **Service Descriptor** message MUST be constructed, which will be published as required, based on higher-layer triggered events:
 - The message MUST use the **SourceID** of the **NfpService**.
 - The message MUST contain one Service Descriptor (SD) structure (section 2.2.9) for the Oob Connector service with the following:
 - ServiceActivationUUID: {E46EDA50-9B5D-41F1-B89E-327B5EA38B16}
 - ServiceVersion: 1
 - ExtendedInfo1: Zeros
 - ExtendedInfo2: Zeros
 - ExtendedPayloadLength: Zero
- The Service Descriptor message MUST contain one SD structure for Session Factory Service Activation with the following values:
 - ServiceActivationUUID: {F1DEBC56-CFBA-4129-983B-7D79499D1A7D}
 - ServiceVersion: 1

Copyright © 2013 Microsoft Corporation.

- ExtendedInfo1: Zeros
- ExtendedInfo2: Zeros
- ExtendedPayloadLength: Zero

3.1.4 Higher-Layer Triggered Events

Higher-layer protocols use this protocol by creating **Session Factory** objects. When an active **Session Factory** object is created, the NfpService MUST ensure that its local **Service Descriptor** (section 2.2.9) is published to the transport. Higher-layer protocols like the Near Field Proximity: Sharing Protocol [MS-NFPS] can also register to handle launching of applications that can use the created socket connection. The implementation for this is not specified.

3.1.5 Message Processing Events and Sequencing Rules

3.1.5.1 Service Descriptor Sequence

The following list defines the required actions of the **NfpService** if an incoming **Service Descriptor** message (section 2.2.8) is received on a transport link:

- The local Service Descriptor (SD) structure (section 2.2.9) MUST be published, unless it has already been sent on the current active transport link.
- The local **SD** MUST NOT be published twice on any one active transport link.
- If the incoming SD has an Oob Connector service UUID, the Oob Connector exchange MUST be followed as specified in section <u>3.1.5.2</u>.
- If the incoming SD has a Session Factory service UUID and an Oob Connector service UUID, the Session Factory exchange MUST be followed as specified in section <u>3.1.5.5</u>.

3.1.5.2 Oob Connector Exchange

The following sequence defines the required actions of the **NfpService** if a **Service Descriptor** message (section 2.2.8) is received on the transport link with a valid **Oob Connector** service UUID:

- 1. If the received **ActivationChannelID** is equal to the **SourceID** of the local **NfpService**, then this sequence MUST be stopped: Steps 2 and later MUST NOT occur.
- 2. If the received **ActivationChannelID** is greater than or equal to the **SourceID** of the local **NfpService**, then this sequence MUST be stopped: Steps 3 and later MUST NOT occur.

Note The remote peer is the one that continues the **Oob Connector** exchange.

- 3. A new **Oob Connector** object SHOULD be created in the **NfpService** list with the following attributes, unless one already exists with a **RemoteSourceID** equal to the **ActivationChannelID** field of the received **Service Descriptor** message:
 - 1. Role: Connector
 - 2. RemoteSourceID: The received ActivationChannelID
 - 3. **OobConnectorID**: This ID is randomly generated.
 - 4. WfdPeerConnected: FALSE

Copyright © 2013 Microsoft Corporation.

- 4. If the **Oob Connector** object has the listener role, then this sequence MUST be stopped: Steps 5 and later MUST NOT occur.
- 5. Reset the following **Oob Connector** object variables:
 - 1. **State**: WaitingForAck
 - 2. LocalAddresses: The list of local addresses collected from the local machine.
- 6. If the **Oob Connector** object's **WfdPeerConnected** field is equal to FALSE, construct a new Wi-Fi Direct Connect BLOB for the local machine.
- 7. Subscribe to the **Oob Connector Service ACK** message (section <u>2.2.4</u>) on the **Oob Connector** object's **OobConnectorID**.
- 8. Construct an **Oob Connector Service Activation** message (section 2.2.5):
 - 1. Set the ServiceActivationHeader, WiFiDirectConnectBlobLength, and WiFiDirectConnectBlob fields.
 - 2. Use the **Oob Connector** object's **OobConnectorID** element to set the **ReplyChannelID** field.
 - 3. Use the **Oob Connector** object's **LocalAddresses** element to set the various **Address** fields.
- 9. Publish the **Oob Connector Service Activation** message on the received **ActivationChannelID**.
- 10.If the **OobConnectorProtocolTimer** (section <u>3.1.2</u>) has not yet fired for this **Oob Connector** object, stop the timer and decrement the **Oob Connector** object's **ReferenceCount** element by 1.
- 11.Start the **OobConnectorProtocolTimer** for this **Oob Connector** object.

12.Increment the **Oob Connector** object's **ReferenceCount** element by 1.

3.1.5.3 Handling Oob Connector Service Activation Messages

The following sequence defines the required actions of the **NfpService** if an **Oob Connector Service Activation** message (section 2.2.5) is received on the transport link on the **SourceID** of the **NfpService**.

- A new **Oob Connector** object SHOULD be created in the NfpService's list with the following attributes, unless one already exists with a **RemoteSourceID** equal to the **SourceID** field in the **Service Activation** header (section <u>2.2.7</u>) within the received message:
 - 1. Role: Listener
 - 2. **RemoteSourceID**: The **SourceID** field in the **Service Activation** header within the received message.
 - 3. WfdPeerConnected: FALSE
- 2. If the **Oob Connector** object has the connector role, then this sequence MUST be stopped: Steps 5 and later MUST NOT occur.
- 3. Reset the following **Oob Connector** object variables:

Copyright © 2013 Microsoft Corporation.

- 1. **State**: WaitingForTransmit
- 2. **OobConnectorID**: Copy this value from the **ReplyChannelID** field of the received message.
- 3. LocalAddresses: The list of local addresses collected from the local machine.
- 4. **RemoteAddresses**: Copy this value from the various **Address** fields of the received message.
- 4. If the **Oob Connector** object's **WfdPeerConnected** field is equal to FALSE, construct a new Wi-Fi Direct Listen BLOB for the local machine.
- If the Oob Connector object's WfdPeerConnected field is equal to FALSE, the NfpService can attempt to use the Wi-Fi Direct Connect BLOB to start listening for Wi-Fi Direct OOB pairing connections.
- 6. Construct an **Oob Connector Service ACK** message (section 2.2.4):
 - 1. Set the **WiFiDirectConnectBlobLength** and **WiFiDirectConnectBlob** fields as specified in section <u>2.2.4</u>.
 - 2. Use the **Oob Connector** object's **LocalAddresses** to set the various address fields.
- 7. Publish the **Oob Connector Service ACK** message on the received **ReplyChannelID**.

If the transport link indicates that this message is transmitted prior to the **OobConnectorProtocolTimer** expiring for this **Oob Connector** object, then the **Oob Connector** object's **State** moves to Ready.

- 1. If the **OobConnectorProtocolTimer** has not yet fired for this **Oob Connector** object, stop the timer and decrement the **Oob Connector ReferenceCount** by 1.
- 2. Start the **OobConnectorProtocolTimer** for this **Oob Connector** object.
- 3. Increment the **Oob Connector ReferenceCount** by 1.

3.1.5.4 Handling Oob Connector Service ACK Messages

The following sequence defines the required actions of the **NfpService** if an **Oob Connector Service ACK** message (section 2.2.4) is received on the transport link on the **OobConnectorID** ChannelID of a specific **Oob Connector** object:

- 1. If the **Oob Connector** object's **State** is NOT WaitingForAck, then this sequence MUST be stopped: Steps 2 and later MUST NOT occur.
- 2. Reset the following **Oob Connector** object variables:
 - 1. State: Ready
 - 2. **RemoteAddresses**: Copy this value from the various **Address** fields of the received message.
- If the Oob Connector object's WfdPeerConnected field is equal to FALSE, the NfpService can attempt to use the received Wi-Fi Direct listener BLOB and the previously sent Wi-Fi Direct connector BLOB to initiate a Wi-Fi Direct OOB pairing connection.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

3.1.5.5 Session Factory Exchange

The following sequence defines the required actions of the **NfpService** if a **Service Descriptor** message (section 2.2.8) is received on the transport link with both a valid **Oob Connector** service UUID and a valid **Session Factory** service UUID. Both MUST be present because the **Session Factory** service relies on the **Oob Connector** exchange.

For each **Session Factory** object (section 3.1.1.3) in the **NfpService SessionFactoryList** where the context of the system indicates that the user intends to use the **Session Factory** to link with the Peer, the following can be performed:

- 1. Construct a Session Factory Service Activation message (section 2.2.12):
 - 1. Set the **Service Activation** header (section 2.2.7), **ClientPreference**, and **Reserved** fields.
 - 2. Use the **Session Factory** object's **SessionFactoryID** to set the **ReplyChannelID** field in the message.
 - 3. If the context of the system indicates that the user wants to have the peer launch and/or acquire an application able to handle the Session connection, then the L (Launch) flag can be set.
 - 4. Use the **Session Factory** object's **AppID** and **AlternateIDList** to add one or more **AppInfo** structures (section <u>2.2.2</u>) to the message.
- Ensure that a subscription is made on the **ReplyChannelID** (also known as the SessionFactoryID) that handles Session Activation messages (section <u>2.2.11</u>).

3.1.5.6 Handling Session Factory Service Activation

The following sequence defines the required actions of the **NfpService** if a **Session Factory Service Activation** message (section 2.2.12) is received on the transport link on the **SourceID** of the **NfpService**. For each **Session Factory** object (section 3.1.1.3) in the **NfpService SessionFactoryList**:

 If the received message does not contain an AppInfo structure (section 2.2.2) with the local platform qualifier and the Session Factory object's AppID field, then this sequence MUST be aborted.

Note Although the **AppID** string is platform-dependent, a binary comparison can be performed.

- 1. If the received **ClientPreference** field is greater than the local client preference, then this sequence MUST be aborted.
- 2. If the received **ReplyChannelID** field is greater than the **Session Factory** object's **SessionFactoryID**, then this sequence MUST be aborted.
- If a Session object (section <u>3.1.1.4</u>) can be found in the Session Factory object's SessionList with a State equal to Ready and a RemoteSessionFactoryID equal to the received ReplyChannelID field, then this sequence MUST be aborted.
- If the Session Factory Service Activation message that is received contains a Role field, its value SHOULD
 be checked for compatibility according to the Role Compatibility constants (section 2.2.6). If the Role value is incompatible, then this sequence MUST be aborted.
- 5. A higher-level protocol can begin at this step.

Copyright © 2013 Microsoft Corporation.

[[]MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

- 6. Create a new **Session** object and add it to the **Session Factory** object's **SessionList** with the following attributes:
 - 1. Role: Client
 - 2. State: WaitingForAck
 - 3. **SessionID**: This is randomly generated.
 - 4. **RemoteSessionFactoryID**: Set to the **ReplyChannelID** field of the received message.
 - 5. **PrivateKey/PublicKey**: Generate 256-bit key pair using the Elliptic-Curve-Diffie-Hellman (ECDH) P256 convention [NSA].
 - 6. SharedSecretKey: Zeroed
- Attempt to get a reference link to the **Oob Connector** object indexed by the **SourceID** field in the **Service Activation** header (section <u>2.2.7</u>) within the received **Session Factory Service Activation** message.

If this is not yet available, it MUST be set if it becomes available prior to the **SessionProtocolTimer** expiration for this **Session** object.

- 1. Start the **SessionProtocolTimer** for this **Session** object.
- 2. Construct a **Session Activation** message (section 2.2.11):
 - 1. Set the **SourceID** and various **Reserved** fields.
 - Set the ExtensionCount and ExtensionStructures fields. If the Session Factory Service Activation message that is received contains a Role field, the Extension structure in the ExtensionStructures field SHOULD be formatted as specified in section <u>2.2.11</u>.
 - 3. Use the Session Factory object's SessionFactoryID to set the ActivatedSession FactoryID field.
 - 4. Use the **Session** object's **SessionID** to set the **ReplyChannelID** field.
 - 5. Use the **Session** object's **PublicKey** to set the **ECDHPublicKeyMagicNumber** field.
- 3. Subscribe to **Session ACK** messages (section <u>2.2.10</u>) using the **Session** object's **SessionID** as the ChannelID.
- 4. Publish the **Session Activation** message to the received **ReplyChannelID**.

When the transport indicates that this message has been transmitted, the **Session** object's **State** moves to Ready.

3.1.5.7 Handling Session Activation

The following sequence defines the required actions of the **NfpService** if a **Session Activation** message (section 2.2.11) is received on the transport link on the **ReplyChannelID** of a specific **Session Factory** object (section 3.1.1.3):

 If a Session object (section <u>3.1.1.4</u>) can be found in the Session Factory object's SessionList with a State equal to Ready and a RemoteSessionFactoryID equal to the received ActivatedSessionFactoryID field, then this sequence MUST be aborted.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

- 2. Create a new **Session** object and add it to the **Session Factory** object's **SessionList** with the following attributes:
 - 1. Role: Server
 - 2. **State**: WaitingForTransmit
 - 3. SessionID: Set to the received ReplyChannelID
 - 4. **RemoteSessionFactoryID**: Set to the **ActivatedSessionFactoryID** field of the received message
 - 5. **PrivateKey/PublicKey**: Generate 256-bit key pair using the Elliptic-Curve-Diffie-Hellman (ECDH) P256 convention [NSA].
 - 6. **SharedSecretKey**: Derive using the SHA256 **key derivation** algorithm with the above **PrivateKey** and **PublicKey** pair and the **ECDH Public Key** field of the received message.
- 3. Start the SessionProtocolTimer for this Session object.
- 4. Construct a **Session ACK** message (section 2.2.10):
 - 1. Set the **Reserved** and **Extension** fields.
 - 2. Use the Session object's PublicKey to set the ECDH Public Key field.
 - 3. Use the Session Factory object's TcpPort to set the TCP Port field.
 - 4. Use the Session Factory object's RfcommPort to set the RFCOMM Port field.
- 5. Publish the Session ACK message to the received ReplyChannelID.

If the transport link indicates that this message is transmitted prior to the **SessionProtocolTimer** expiring for this **Session** object, then the **Session** object's **State** moves to Ready.

The **Session** object can then be used by higher-level protocols to create connections to the peer.

3.1.5.8 Handling Session ACK Messages

The following sequence defines the required actions of the **NfpService** if a **Session ACK** message (section 2.2.10) is received on the transport link on the **SessionID** ChannelID of a specific **Session** object (section 3.1.1.4):

- 1. If the **Session** object's **State** is not WaitingForAck, then this sequence MUST be aborted.
- Derive the SharedSecretKey using the SHA256 key derivation algorithm (see P256 curve in [NSA]) with the Session object's PrivateKey and PublicKey pair and the ECDHPublicKeyMagicNumber field of the received message.
- 3. The TCP Port field of the received message is copied to the Session object.
- 4. The **RFCOMM Port** field of the received message is copied to the **Session** object.
- 5. The **Session** object's **State** moves to Ready.
- 6. The **Session** object can be used by higher-level protocols to create connections to the peer.

Copyright © 2013 Microsoft Corporation.

3.1.5.9 Handling the Accept Header

The following sequence defines the required actions following the activation of the session:

- 1. The server MUST listen on transports according to information that was exchanged with the client in earlier steps of the protocol.
- 2. The client MUST attempt to connect to the server on all the transports that the server is listening on.
- 3. The server chooses the best connection and accepts it.
- On connection establishment, the client MUST send an Accept Header (section 2.2.1) to the server.
- On receipt of the Accept Header, the server MUST validate the SessionID from the Accept Header by comparing it to the ReplyChannelID that it received from the client in the Session Activation message (section 2.2.11).
- 6. If the IDs match, the server MUST send the **Accept Header** back to the client. If the IDs do not match, the server MUST abort the connection.
- The client MUST validate the Accept Header received from the server by comparing it to the Accept Header it sent before. If the Accept Headers match, the negotiation is complete; otherwise, the client MUST abort the connection.

3.1.6 Timer Events

The following timer events are associated with the timers defined by this protocol (section 3.1.2).

- SessionProtocolTimer: If this timer fires when the associated Session object (section 3.1.1.4) State is WaitingForAck or WaitingForTransmit, the object transitions to the Terminated state. This Session object is not usable by higher-level protocols. If this timer fires when the Session object State is Ready, the timer is ignored.
- **OobConnectorProtocolTimer:** If this timer fires when the associated **Oob Connector** object (section <u>3.1.1.2</u>) **State** is WaitingForAck or WaitingForTransmit, the object **State** transitions to Incomplete. If this timer fires when the **Oob Connector** object **State** is any other value, the timer is ignored.
- **OobConnectorKeepAliveTimer:** If this timer fires before the associated **Oob Connector** object **State** transitions out of Incomplete, the reference logged at initialization SHOULD be released. If there are no other references to the object, the object SHOULD be destroyed.
- **SessionFactoryKeepAliveTimer:** An independent timer for each **Session Factory** object (section <u>3.1.1.3</u>), which is started when a **Session Factory** object is created. If it fires before a client takes ownership of the object, the **Session Factory** object SHOULD be deleted.

3.1.7 Other Local Events

None.

4 Protocol Examples

The following scenario shows a successful real-time connection established between two peers, Peer A and Peer B. The example demonstrates this through a hypothetical application called Adventure Works, made by Contoso. This example assumes that the underlying transport works like NFC, in that the transport is activated when two peers become proximate. Peer A has the **NfpService** (section 3.1.1.1) initialized with an active **SessionFactory** object (section 3.1.1.3) that is configured to establish a session when the transport is next activated. Peer A is running on a platform called "Windows". Peer B merely has the **NfpService** initialized, and it is running on a platform called "Android".

Peer A's **NfpService** happens to have a **SourceID** = 0x80, 0x29, 0x84, 0xF4, 0xD6, 0x0E, 0x8D, 0x2B. The base64 encoding for this **SourceID** is "gCmE9NYOjSs".

Peer B's **NfpService** happens to have a **SourceID** = 0xF3, 0x88, 0xC0, 0x6B, 0xE9, 0xCF, 0xD4, 0xDE. The base64 encoding for this **SourceID** is "84jAa+nP1N4".

In this example, the application is uniquely identified on each platform by the following IDs:

"Android" - "Contoso-Adventure Works-3/6/2012"

"Windows" - "Contoso%AdventureWorksApp"

"WinPhone" - "{8342DF32-AD41-8993-927F-CACE4A295751}

Initially, Peer A's Session Factory object has the following abstract data model elements:

SessionList: Empty; that is, no **Session** objects (section <u>3.1.1.4</u>) that represent connections to Peer B.

AppID: "Windows" - "Contoso%AdventureWorksApp"

AlternateIDList: "Android" - "Contoso-Adventure Works-3/6/2012", "WinPhone" - "{8342DF32-AD41-8993-927F-CACE4A295751}

Launch: TRUE.

SessionFactoryID: 0x6c331689, c15ca44b. This number is specified as random; however for this example, this number was specifically chosen to make it easy to recognize.

TcpPort: 55555.

RfcommPort: 5.

ReferenceCount: 1 (referenced by the running Adventure Works app).

4.1 Transport Activation and Initial Service Descriptor

When the underlying transport is activated, the protocol begins transmitting. Peer A begins by publishing its pre-initialized **Service Descriptor** message (section <u>2.2.8</u>) on the well-known channel: "Windows.windows.com/SD". Length = 56 bytes.

4.2 Peer A Service Descriptor Received by Peer B

When a valid **Service Descriptor (SD)** structure (section 2.2.9) is received by Peer B, it will immediately respond with its own **Service Descriptor** message (section 2.2.8) on the same well-known channel: "Windows.windows.com/SD". Length = 56 bytes.

4.4 Peer A Receives Oob Connector Service Activation Message, Responds with Oob Connector Service ACK

When Peer B's valid **Oob Connector Service Activation** message (section 2.2.5) is received by Peer A, it responds with a **Oob Connector Service ACK** message (section 2.2.4) on the received **ReplyChannelID**, which is the **OobConnectorID** of Peer B's newly created **Oob Connector** object (section 3.1.1.2): "Windows.bcso+pFofkc". Length = 106 bytes.

4.5 Peer A Session Factory Service Activation Received by Peer B, Responds with Session Activation

When Peer A's valid **Session Factory Service Activation** message (section 2.2.12) is received by Peer B, it responds by launching the Adventure Works App, creating a **Session Factory** object, creating a **Session** object (section 3.1.1.4), and replying with a **Session Activation** message (section 2.2.11) on the received **ReplyChannelID**, which is the **SessionFactoryID** of Peer A's **Session Factory** object (section 3.1.1.3) for the Adventure Works application: "Windows.bDMWicFcpEs". Length = 96 bytes.

4.6 Peer B Session Activation Received by Peer A, Responds with Session ACK

When Peer B's valid **Session Activation** message (section 2.2.11) is received by Peer A, it responds with a **Session ACK** message (section 2.2.10) on the received **ReplyChannelID**, which is the **SessionID** of Peer B's newly created **Session** object (section 3.1.1.4): "Windows.rhlJshr/7Ew". Length = 76 bytes.

4.7 Peer A Session ACK Received by Peer B, Begins Connection Validation

When Peer A's valid **Session ACK** message (section 2.2.10) is received by Peer B, it responds with an **Accept Header** (section 2.2.1) on the **SessionID** of its **Session** object (section 3.1.1.4): "Windows.rhlJshr/7Ew". The **ConnectionType** field indicates that this is an IPv4 connection. This begins the connection validation handshake.

0	1	2	3	4	5	6	7	8	9	1 0	1	2	3	4	5	6	7	8	9	2 0	1	2	3	4	5	6	7	8	9	3 0	1
												Ses	sio	nII) =	"rh	IJsh	r/7l	Ew"												
												0>	ĸАЕ	, 0×	:19,	0x4	49,	0xB	32

												0:	x00	, 0×	:00,	0x(00,	0x0	2												

4.8 Peer B Accept Header Received by Peer A, Completes Connection Validation

When Peer B's valid **Accept Header** (section 2.2.1) is received by Peer A, it responds by saving the structure in its **NfpService** state element **HandshakeData** and returning the identical **Accept Header** shown in section 4.7. This completes the connection validation handshake.

6 Appendix A: Product Behavior

The information in this specification is applicable to the following Microsoft products or supplemental software. References to product versions include released service packs:

- Windows 8 operating system
- Windows 8.1 operating system

Exceptions, if any, are noted below. If a service pack or Quick Fix Engineering (QFE) number appears with the product version, behavior changed in that service pack or QFE. The new behavior also applies to subsequent service packs of the product unless otherwise specified. If a product edition appears with the product version, behavior is different in that product edition.

Unless otherwise specified, any statement of optional behavior in this specification that is prescribed using the terms SHOULD or SHOULD NOT implies product behavior in accordance with the SHOULD or SHOULD NOT prescription. Unless otherwise specified, the term MAY implies that the product does not follow the prescription.

<1> Section 2.2.6: Windows 8: Role compatibility checking is not supported.

<2> Section 2.2.11: Windows 8: The Role field in the Session Factory Service Activation message is not supported.

<3> Section 2.2.12: Windows 8: The host or client ServiceActivationUUID value is not supported.

<4> Section 2.2.12: Windows 8: The Role field is not supported.

<5> Section 3.1.2: Windows: The default value is 10 seconds.

<6> Section 3.1.2: Windows: The default value is 10 seconds.

<7> Section 3.1.2: Windows: A timeout value of 10 minutes is used.

<8> Section 3.1.2: Windows: A timeout value of 6 minutes is used.

<9> Section 3.1.5.6: Windows 8: The Role field in the Session Factory Service Activation message is not supported.

7 Change Tracking

This section identifies changes that were made to the [MS-NFPB] protocol document between the January 2013 and August 2013 releases. Changes are classified as New, Major, Minor, Editorial, or No change.

The revision class **New** means that a new document is being released.

The revision class **Major** means that the technical content in the document was significantly revised. Major changes affect protocol interoperability or implementation. Examples of major changes are:

- A document revision that incorporates changes to interoperability requirements or functionality.
- An extensive rewrite, addition, or deletion of major portions of content.
- The removal of a document from the documentation set.
- Changes made for template compliance.

The revision class **Minor** means that the meaning of the technical content was clarified. Minor changes do not affect protocol interoperability or implementation. Examples of minor changes are updates to clarify ambiguity at the sentence, paragraph, or table level.

The revision class **Editorial** means that the language and formatting in the technical content was changed. Editorial changes apply to grammatical, formatting, and style issues.

The revision class **No change** means that no new technical or language changes were introduced. The technical content of the document is identical to the last released version, but minor editorial and formatting changes, as well as updates to the header and footer information, and to the revision summary, may have been made.

Major and minor changes can be described further using the following change types:

- New content added.
- Content updated.
- Content removed.
- New product behavior note added.
- Product behavior note updated.
- Product behavior note removed.
- New protocol syntax added.
- Protocol syntax updated.
- Protocol syntax removed.
- New content added due to protocol revision.
- Content updated due to protocol revision.
- Content removed due to protocol revision.
- New protocol syntax added due to protocol revision.

- Protocol syntax updated due to protocol revision.
- Protocol syntax removed due to protocol revision.
- New content added for template compliance.
- Content updated for template compliance.
- Content removed for template compliance.
- Obsolete document removed.

Editorial changes are always classified with the change type Editorially updated.

Some important terms used in the change type descriptions are defined as follows:

- Protocol syntax refers to data elements (such as packets, structures, enumerations, and methods) as well as interfaces.
- Protocol revision refers to changes made to a protocol that affect the bits that are sent over the wire.

The changes made to this document are listed in the following table. For more information, please contact protocol@microsoft.com.

Section	Tracking number (if applicable) and description	Major change (Y or N)	Change type
<u>1.3</u> <u>Overview</u>	Enhanced the explanation of "winning peer". Removed the SD acronym.	N	Content updated.
<u>1.3</u> <u>Overview</u>	Introduced the concept of connection validation for L3 connections.	Y	Content updated.
<u>1.3.4</u> <u>Connection</u> <u>Validation</u>	Added section 1.3.4.	Y	New protocol syntax added.
<u>1.4</u> <u>Relationship to Other</u> <u>Protocols</u>	Removed the SD acronym.	N	Content updated.
<u>1.7</u> <u>Versioning and</u> <u>Capability</u> <u>Negotiation</u>	Indicated that no authentication is provided, because this is unauthenticated Diffie-Hellman.	N	Content updated.
<u>1.8.1</u> <u>Service Descriptor</u> <u>Entries</u>	Removed platform-specific content. Added references to the Service Descriptor (SD) structure.	N	Content updated.
<u>1.9</u> <u>Standards</u> <u>Assignments</u>	Removed pub/sub channel, which was not assigned by a standards body or other assignment authority.	N	Content updated.
2.2.1 Accept Header	Added section 2.2.1.	Y	New protocol syntax added.

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

Section	Tracking number (if applicable) and description	Major change (Y or N)	Change type
2.2.2 AppInfo Structure	Changed character encoding type for platform qualifier namespace string.	N	Content updated.
2.2.4 Oob Connector Service ACK Message	Changed [RFC4380] from a normative to an informative reference.	N	Content updated.
2.2.5 Oob Connector Service Activation Message	Replaced the glossary term Message Authentication Code with Media Access Control.	N	Content updated.
2.2.6 <u>Role Compatibility</u> <u>Constants</u>	Added Role Compatibility constants.	Y	New protocol syntax added.
2.2.7 Service Activation Header	Changed prescriptive verb. Removed time-relative declaration.	N	Content updated.
2.2.8 Service Descriptor Message	Moved the Service Descriptor into its own section 2.2.3. Added references to the Service Descriptor (SD) structure. Changed the wording governing the support for prior versions.	Y	Content updated.
2.2.9 Service Descriptor Structure	Moved the Service Descriptor into its own section from the Service Descriptor Message section 2.2.5 (previously 2.2.4), because it is referenced as a separate entity elsewhere in the document.	Y	New content added.
2.2.10 Session ACK Message	Added informative reference for P256 convention in cryptography,	N	Content updated.
2.2.10 Session ACK Message	67195 Changed the statement of length limitation to refer to the Session ACK message.	N	Content updated.
2.2.11 Session Activation Message	Added informative reference for P256 convention in cryptography,	N	Content updated.
2.2.11 Session Activation Message	Added content for Windows 8.1 and Windows Server 2012 R2.	Y	Content updated.
2.2.12 Session Factory Service Activation Message	Added content for Windows 8.1 and Windows Server 2012 R2.	Y	Content updated.
<u>3.1</u> <u>Peer Details</u>	Added summary of protocol roles. Moved ADM information to ADM section 3.1.1.	N	Content updated.
<u>3.1.1</u>	Moved ADM information from section 3.1.	Ν	Content

[MS-NFPB] — v20130722 Near Field Proximity: Bidirectional Services Protocol

Copyright © 2013 Microsoft Corporation.

Section	Tracking number (if applicable) and description	Major change (Y or N)	Change type
Abstract Data Model			updated.
<u>3.1.1.1</u> <u>NfpService</u>	Added Accept Header information to ADM.	Y	New protocol syntax added.
3.1.1.3 Session Factory Object	Added string encoding descriptor,	N	Content removed for template compliance.
<u>3.1.2</u> <u>Timers</u>	67189 Added SessionFactoryKeepAlive timer and moved timout values to product behavior notes.	N	Content updated.
<u>3.1.3</u> Initialization	Added references to the Service Descriptor (SD) structure.	N	Content updated.
3.1.5.3 Handling Oob Connector Service Activation Messages	67190 Changed the State to WaitingForTransmit.	N	Content updated.
3.1.5.6 Handling Session Factory Service Activation	Added informative reference for P256 convention in cryptography, Specified type of comparison for AppID string.	N	Content updated.
3.1.5.6 Handling Session Factory Service Activation	Added content for Windows 8.1 and Windows Server 2012 R2.	Y	Content updated.
3.1.5.7 Handling Session Activation	Added informative reference for P256 convention in cryptography,	N	Content updated.
3.1.5.8 Handling Session ACK Messages	Provided informative reference for SHA256 key derivation.	N	Content updated.
<u>3.1.5.9</u> <u>Handling the Accept</u> <u>Header</u>	Added section 3.1.5.9.	Y	New protocol syntax added.
3.1.6 Timer Events	67189 Consolidated timer events in one section for parallelism. Added OobConnectorKeepAliveTimer and SessionFactoryKeepAlive timer.	Y	Protocol syntax updated.
<u>4.7</u> Peer A Session ACK Received by Peer B, Begins Connection Validation	Added section 4.7.	Y	New content added.
