Remote Certificate Mapping Protocol

Intellectual Property Rights Notice for Open Specifications Documentation

- **Technical Documentation.** Microsoft publishes Open Specifications documentation (“this documentation”) for protocols, file formats, data portability, computer languages, and standards support. Additionally, overview documents cover inter-protocol relationships and interactions.
- **Copyrights.** This documentation is covered by Microsoft copyrights. Regardless of any other terms that are contained in the terms of use for the Microsoft website that hosts this documentation, you can make copies of it in order to develop implementations of the technologies that are described in this documentation and can distribute portions of it in your implementations that use these technologies or in your documentation as necessary to properly document the implementation. You can also distribute in your implementation, with or without modification, any schemas, IDLs, or code samples that are included in the documentation. This permission also applies to any documents that are referenced in the Open Specifications documentation.
- **No Trade Secrets.** Microsoft does not claim any trade secret rights in this documentation.
- **Patents.** Microsoft has patents that might cover your implementations of the technologies described in the Open Specifications documentation. Neither this notice nor Microsoft's delivery of this documentation grants any licenses under those patents or any other Microsoft patents. However, a given Open Specifications document might be covered by the Microsoft [Open Specifications Promise](#) or the [Microsoft Community Promise](#). If you would prefer a written license, or if the technologies described in this documentation are not covered by the Open Specifications Promise or Community Promise, as applicable, patent licenses are available by contacting iplg@microsoft.com.
- **License Programs.** To see all of the protocols in scope under a specific license program and the associated patents, visit the [Patent Map](#).
- **Trademarks.** The names of companies and products contained in this documentation might be covered by trademarks or similar intellectual property rights. This notice does not grant any licenses under those rights. For a list of Microsoft trademarks, visit www.microsoft.com/trademarks.
- **Fictitious Names.** The example companies, organizations, products, domain names, email addresses, logos, people, places, and events that are depicted in this documentation are fictitious. No association with any real company, organization, product, domain name, email address, logo, person, place, or event is intended or should be inferred.

Reservation of Rights. All other rights are reserved, and this notice does not grant any rights other than as specifically described above, whether by implication, estoppel, or otherwise.

Tools. The Open Specifications documentation does not require the use of Microsoft programming tools or programming environments in order for you to develop an implementation. If you have access to Microsoft programming tools and environments, you are free to take advantage of them. Certain Open Specifications documents are intended for use in conjunction with publicly available standards specifications and network programming art and, as such, assume that the reader either is familiar with the aforementioned material or has immediate access to it.

Support. For questions and support, please contact dochelp@microsoft.com.

Revision Summary

Date	Revision History	Revision Class	Comments
3/2/2007	1.0	Major	Updated and revised the technical content.
4/3/2007	1.1	Minor	Clarified the meaning of the technical content.
5/11/2007	1.2	Minor	Addressed EU feedback
6/1/2007	1.3	Minor	Clarified the meaning of the technical content.
7/3/2007	1.3.1	Editorial	Changed language and formatting in the technical content.
8/10/2007	1.3.2	Editorial	Changed language and formatting in the technical content.
9/28/2007	1.3.3	Editorial	Changed language and formatting in the technical content.
10/23/2007	2.0	Major	Converted document to unified format.
1/25/2008	2.0.1	Editorial	Changed language and formatting in the technical content.
3/14/2008	2.0.2	Editorial	Changed language and formatting in the technical content.
6/20/2008	2.1	Minor	Clarified the meaning of the technical content.
7/25/2008	2.2	Minor	Clarified the meaning of the technical content.
8/29/2008	2.2.1	Editorial	Changed language and formatting in the technical content.
10/24/2008	2.2.2	Editorial	Changed language and formatting in the technical content.
12/5/2008	3.0	Major	Updated and revised the technical content.
1/16/2009	3.0.1	Editorial	Changed language and formatting in the technical content.
2/27/2009	3.0.2	Editorial	Changed language and formatting in the technical content.
4/10/2009	3.0.3	Editorial	Changed language and formatting in the technical content.
5/22/2009	4.0	Major	Updated and revised the technical content.
7/2/2009	5.0	Major	Updated and revised the technical content.
8/14/2009	5.0.1	Editorial	Changed language and formatting in the technical content.
9/25/2009	5.1	Minor	Clarified the meaning of the technical content.
11/6/2009	5.1.1	Editorial	Changed language and formatting in the technical content.
12/18/2009	6.0	Major	Updated and revised the technical content.
1/29/2010	6.1	Minor	Clarified the meaning of the technical content.
3/12/2010	6.1.1	Editorial	Changed language and formatting in the technical content.
4/23/2010	6.1.2	Editorial	Changed language and formatting in the technical content.
6/4/2010	7.0	Major	Updated and revised the technical content.
7/16/2010	7.0	None	No changes to the meaning, language, or formatting of the technical content.

Date	Revision History	Revision Class	Comments
8/27/2010	7.0	None	No changes to the meaning, language, or formatting of the technical content.
10/8/2010	7.0	None	No changes to the meaning, language, or formatting of the technical content.
11/19/2010	7.0	None	No changes to the meaning, language, or formatting of the technical content.
1/7/2011	7.0	None	No changes to the meaning, language, or formatting of the technical content.

1 Introduction

This document specifies the Remote Certificate Mapping Protocol. The Remote Certificate Mapping Protocol is used by servers that authenticate users via X.509 certificates, as specified in [X509]. This protocol allows the server to use a directory, database, or other technology to map the user's X.509 certificate to a security principal. This protocol returns the authorization information associated with the security principal in the form of a privilege attribute certificate (PAC), as specified in [MS-PAC], that represents the user's identity and group memberships. Throughout this document, little-endian format applies unless otherwise stated.

Sections 1.5, 1.8, 1.9, 2, and 3 of this specification are normative. All other sections and examples in this specification are informative.

1.1 (Updated Section) Glossary

This document uses the following terms:

Active Directory: A The Windows implementation of a general-purpose network directory service. Active Directory also refers to the Windows implementation of a directory service, which uses LDAP as its primary access protocol. Active Directory stores information about a variety of objects in the network. User such as user accounts, computer accounts, groups, and all related credential information used by the Windows implementation of Kerberos are stored in Active Directory. [MS-KILE]. Active Directory is either deployed as Active Directory Domain Services (AD DS) or Active Directory Lightweight Directory Services (AD LDS). [MS-ADTS] describes both forms. For more information, see [MS-AUTHSOD] section 1.1.1.5.2, Lightweight Directory Access Protocol (LDAP) versions 2 and 3, Kerberos, and DNS, which are both described in [MS-ADOD]: Active Directory Protocols Overview.

distinguished name (DN): A name that uniquely identifies an object by using the relative distinguished name (RDN) for the object, and the names of container objects and domains that contain the object. The distinguished name (DN) identifies the object and its location in a tree.

domain: A set of users and computers sharing a common namespace and management infrastructure. At least one computer member of the set must act as a domain controller (DC) and host a member list that identifies all members of the domain, as well as optionally hosting the Active Directory service. The domain controller provides authentication of members, creating a unit of trust for its members. Each domain has an identifier that is shared among its members. For more information, see [MS-AUTHSOD] section 1.1.1.5 and [MS-ADTS].

domain controller (DC): The service, running on a server, that implements Active Directory, or the server hosting this service. The service hosts the data store for objects and interoperates with other DCs to ensure that a local change to an object replicates correctly across all DCs. When Active Directory is operating as Active Directory Domain Services (AD DS), the DC contains full NC replicas of the configuration naming context (config NC), schema naming context (schema NC), and one of the domain NCs in its forest. If the AD DS DC is a global catalog server (GC server), it contains partial NC replicas of the remaining domain NCs in its forest. For more information, see [MS-AUTHSOD] section 1.1.1.5.2 and [MS-ADTS]. When Active Directory is operating as Active Directory Lightweight Directory Services (AD LDS), several AD LDS DCs can run on one server. When Active Directory is operating as AD DS, only one AD DS DC can run on one server. However, several AD LDS DCs can coexist with one AD DS DC on one server. The AD LDS DC contains full NC replicas of the config NC and the schema NC in its forest. The domain controller is the server side of Authentication Protocol Domain Support [MS-APDS].

issuer name: The name of the certificate authority (CA) that signed and issued a certificate. The name is an X.509 format name, as specified in [X509].

little-endian: Multiple-byte values that are byte-ordered with the least significant byte stored in the memory location with the lowest address.

object: In Active Directory, an entity consisting of a set of attributes, each attribute with a set of associated values. For more information, see [MS-ADTS]. See also directory object.

privilege attribute certificate (PAC): A Microsoft-specific authorization data present in the authorization data field of a ticket. The PAC contains several logical components, including group membership data for authorization, alternate credentials for non-Kerberos authentication protocols, and policy control information for supporting interactive logon.

remote procedure call (RPC): A context-dependent communication protocol used primarily between client and server. The term commonly overloaded with has three meanings. Note definitions that much of the industry literature concerning RPC technologies uses this term are often used interchangeably for any of the three meanings. Following are the three definitions: (*) The : a runtime environment providing remote procedure call for communication facilities. The preferred usage for this meaning is "between computers (the RPC runtime". (*) The pattern); a set of request and response message exchanges between computers (the RPC exchange between two parties (typically, a client and a server). The preferred usage for this meaning is "RPC exchange". (*) A : and the single message from an RPC exchange as defined in (the previous definition. The preferred usage for this term is "RPC message".) For more information about RPC, see [C706].

RPC transport: The underlying network services used by the remote procedure call (RPC) runtime for communications between network nodes. For more information, see [C706] section 2.

security principal: A unique entity that is identifiable through cryptographic means by at least one key. It frequently corresponds to a human user, but also can be a service that offers a resource to other security principals. Also referred to as principal.

service principal name (SPN): The name a client uses to identify a service for mutual authentication. (For more information, see [RFC1964] section 2.1.1.) An SPN consists of either two parts or three parts, each separated by a forward slash ('/'). The first part is the service class, the second part is the host name, and the third part (if present) is the service name. For example, "ldap/dc-01.fabrikam.com/fabrikam.com" is a three-part SPN where "ldap" is the service class name, "dc-01.fabrikam.com" is the host name, and "fabrikam.com" is the service name. See [SPNNAMES] for more information about SPN format and composing a unique SPN.

Unicode: A character encoding standard developed by the Unicode Consortium that represents almost all of the written languages of the world. The Unicode standard [UNICODE5.0.0/2007] provides three forms (UTF-8, UTF-16, and UTF-32) and seven schemes (UTF-8, UTF-16, UTF-16 BE, UTF-16 LE, UTF-32, UTF-32 LE, and UTF-32 BE).

user principal name (UPN): A user account name (sometimes referred to as the user logon name) and a domain name that identifies the domain in which the user account is located. This is the standard usage for logging on to a Windows domain. The format is: someone@example.com (in the form of an email address). In Active Directory, the userPrincipalName attribute of the account object, as described in [MS-ADTS].

MAY, SHOULD, MUST, SHOULD NOT, MUST NOT: These terms (in all caps) are used as defined in [RFC2119]. All statements of optional behavior use either MAY, SHOULD, or SHOULD NOT.

1.2 References

Links to a document in the Microsoft Open Specifications library point to the correct section in the most recently published version of the referenced document. However, because individual documents in the library are not updated at the same time, the section numbers in the documents may not match. You can confirm the correct section numbering by checking the Errata.

1.2.1 Normative References

We conduct frequent surveys of the normative references to assure their continued availability. If you have any issue with finding a normative reference, please contact dochelp@microsoft.com. We will assist you in finding the relevant information.

1.3 Overview

The Remote Certificate Mapping Protocol is used in deployments where users rely on [X509] certificates to gain access to resources. After a client authenticates itself to a server using an X.509

certificate, the server uses the Remote Certificate Mapping Protocol to contact a directory to determine the authorization information to use, such as group memberships. The Remote Certificate Mapping Protocol returns a privilege attribute certificate (PAC), as specified in [MS-PAC], that represents the user's identity and group memberships, suitable for making authorization decisions.

There are three methods by which a certificate can be associated with an account for the purposes of authorization.

1. First, the **subjectAltName** field of the X.509 certificate can be treated as a user principal name (UPN) and used as the key, in the database sense, to locate the account record and corresponding authorization information.
2. Second, the issuer and subject names can be taken together as a key, again in the database sense, to locate the account record.
3. Third, the issuer name alone can be used as the lookup key when locating the account record.

The Remote Certificate Mapping Protocol itself consists of a single request/response message pair: `SSL_CERT_LOGON_REQ` (section 2.2.1) and `SSL_CERT_LOGON_RESP` (section 2.2.2). This request/response pair is transferred by using the generic pass-through capability of the Netlogon Remote Protocol, as specified in [MS-NRPC] section 3.2.4.1. The client creates an `SSL_CERT_LOGON_REQ` message that contains the X.509 certificate for which the client wants to obtain the corresponding authorization information and specifies which (or all) of the methods described in the preceding paragraph should be applied. The Remote Certificate Mapping Protocol server uses attributes of this X.509 certificate and the indicated methods by the client to determine the authorization information. Assuming an account is found, the Remote Certificate Mapping Protocol server then creates and returns a PAC, as specified in [MS-PAC], that contains the authorization information in the `SSL_CERT_LOGON_RESP` message to the Remote Certificate Mapping Protocol client.

The Remote Certificate Mapping Protocol specification uses common fields from X.509, as specified in [X509], including **subjectName**, **subjectAltName**, and **issuerName**. An implementer of the Remote Certificate Mapping Protocol has to be familiar with X.509 certificates, in particular the verification and parsing of the certificate to extract the fields listed earlier. For more information about X.509, see [GUTMANN].

1.4 Relationship to Other Protocols

Any protocol that authenticates clients based on public key certificates can make use of the Remote Certificate Mapping Protocol to obtain authorization information about the client. The protocol described in [MS-NRPC] serves as the transport for Remote Certificate Mapping Protocol messages.

The Remote Certificate Mapping Protocol can be used to implement the Secure Sockets Layer/Transport Layer Security (SSL/TLS) protocol, as specified in [RFC2246], and Extensible Authentication (EAP) TLS protocol, as specified in [RFC2716], when client authentication by means of an X.509 certificate is selected as part of the TLS handshake. In the SSL/TLS, authentication of client is optional and is only done when requested by the SSL/TLS server. If the client authentication option is chosen, the SSL/TLS client authenticates itself to the SSL/TLS server using an X.509 certificate.

Figure 1: Protocol relationship diagram.

1.5 Prerequisites/Preconditions

The Remote Certificate Mapping Protocol requires that users have X.509 certificates available to them for authentication. The Remote Certificate Mapping Protocol also requires that a means exists to associate a certificate with a set of authorization data, commonly some form of an account database.<1>

1.6 Applicability Statement

The Remote Certificate Mapping Protocol is applicable in deployments where users have been issued X.509 certificates, as specified in [X509], and a common database for user and machine authorization information. In this type of environment, the Remote Certificate Mapping Protocol is used between the authentication step and authorization step. It enables the server that uses an authentication protocol using X.509 certificates to obtain a PAC, as specified in [MS-PAC], that represents the user's identity and group memberships, suitable for making authorization decisions.

1.7 Versioning and Capability Negotiation

None.

1.8 Vendor-Extensible Fields

The Remote Certificate Mapping Protocol does not have any vendor-extensible fields.

1.9 Standards Assignments

There are no standards assignments in the Remote Certificate Mapping Protocol beyond the standards assignments as specified in [MS-NRPC].

2 Messages

2.1 Transport

The Remote Certificate Mapping Protocol messages are embedded in Netlogon Remote Protocol messages in the logon interface. As a result, the Remote Certificate Mapping Protocol uses the Netlogon RPC transport, as specified in [MS-NRPC] section 2.1.

2.2 Message Syntax

Remote Certificate Mapping Protocol messages are encoded as opaque Binary Large Objects (BLOB) and transported by the generic pass-through capability of the Netlogon Remote Protocol, as specified in [MS-NRPC] section 3.2.4.1.

2.2.1 SSL_CERT_LOGON_REQ Message

The SSL_CERT_LOGON_REQ structure defines a request to map a client certificate to a security principal for the purpose of retrieving the authorization information. All member fields MUST be encoded in little-endian format.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
MessageType																															
Length																															
OffsetCertificate																															
CertLength																															
Flags																															
IssuerCount																															
NameInfo (variable)																															
...																															
Payload (variable)																															
...																															

MessageType (4 bytes): A 32-bit unsigned integer that defines the Remote Certificate Mapping Protocol message type. This member MUST be 0x00000002.

Length (4 bytes): A 32-bit unsigned integer that defines the length, in bytes, of the SSL_CERT_LOGON_REQ request message, including the variable length **NameInfo** and **Payload** sections.

OffsetCertificate (4 bytes): A 32-bit unsigned integer that defines the offset, in bytes, from the beginning of the SSL_CERT_LOGON_REQ request structure to the X.509 certificate, as specified in [X509], in the **Payload** member.

IssuerOffset (4 bytes): A 32-bit unsigned integer that defines the byte offset from the start of the packet to an **IssuerName** in the **Payload** member.

IssuerLength (4 bytes): A 32-bit unsigned integer that defines the length, in bytes, of an **IssuerName** in the **Payload** member.

Payload (variable): A byte-array that contains the data referred to by the **OffsetCertificate** and **IssuerOffset** members. The **IssuerName** members in the **Payload** section has no guaranteed order; order is defined by the **NameInfo** array listed previously. Thus, the data might be packed into the buffer as "Issuer1, Issuer3, Certificate, Issuer2", but the **NameInfo** array would list them as "Issuer1, Issuer2, Issuer3." The actual order is specified in section 3.5.1. The number of issuer names encoded into the **Payload** section is determined by the **IssuerCount** member. Each **IssuerName** MUST be 2-byte aligned.

Certificate: The client's BER-encoded X.509 certificate referred to by the **OffsetCertificate** member. The format of an X.509 certificate is specified in ASN.1 per the X.509 standard, as specified in [X509]. BER encoding is specified in [X690].

IssuerName: The BER-encoded certificate issuer name referred to by an **IssuerOffset**. Each **IssuerName** corresponds to the **issuerName** member of an X.509 certificate in the certificate chain, as specified in [X509]. Only the issuer name is present, not the complete issuer certificate.

2.2.2 SSL_CERT_LOGON_RESP Message

The SSL_CERT_LOGON_RESP structure defines a successful response to an SSL_CERT_LOGON_REQ request. It contains the PAC that is returned to the caller. All member fields MUST be encoded in little-endian order.

0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1
MessageType																															
Length																															
OffsetAuthData																															
AuthDataLength																															
Flags																															
OffsetDomain																															
DomainLength																															
Align																															
Payload (variable)																															
...																															

MessageType (4 bytes): A 32-bit unsigned integer that defines the Remote Certificate Mapping Protocol message type. This member MUST be 0x00000002, matching SSL_CERT_LOGON_REQ.

Length (4 bytes): A 32-bit unsigned integer that defines the length, in bytes, of the SSL_CERT_LOGON_RESP response structure, including the variable **Payload** section.

OffsetAuthData (4 bytes): A 32-bit unsigned integer that defines the offset, in bytes, from the beginning of the SSL_CERT_LOGON_RESP response structure to the PAC, as specified in [MS-PAC], contained in the **Payload** field. This MUST be aligned to an 8-byte boundary.

AuthDataLength (4 bytes): A 32-bit unsigned integer that defines the length, in bytes, of the PAC, as specified in [MS-PAC], contained in the **Payload** field.

Flags (4 bytes): A 32-bit unsigned integer that MUST be 0, and ignored upon receipt. This field was intended for future expansion but was not used.

OffsetDomain (4 bytes): A 32-bit unsigned integer that defines the offset, in bytes, from the beginning of the SSL_CERT_LOGON_RESP request structure to a string of 16-bit Unicode characters comprising the name of the domain used for retrieving the authorization information. The domain name MUST be the NetBIOS name of the account domain.

DomainLength (4 bytes): A 32-bit unsigned integer that defines the length, in bytes, of the domain name referred to by the **OffsetDomain** member. The length does not include any trailing NULL character; because the string is counted, there need not be a trailing NULL.

Align (4 bytes): A 32-bit unsigned integer used to maintain 64-bit alignment. This member MUST be 0x00000000.

Payload (variable): This field contains the PAC, as specified in [MS-PAC], referred to by the **OffsetAuthData** field, and the domain name referred to by the **OffsetDomain** field.

2.3 Constants

The following constants are used in this specification.

Symbolic Name	Value	Definition
STATUS_LOGON_FAILURE	0xC000006D	A logon failure occurred.

2.4 Directory Service Schema Elements

The Remote Certificate Mapping Protocol (RCMP) accesses the Directory Service schema classes and attributes listed in the following table.

For the syntactic specifications of the following **<Class>** or **<Class><Attribute>** pairs, refer to [MS-ADTS], [MS-ADA1], [MS-ADA3].

Class	Attribute
computer	servicePrincipalName userPrincipalName
user	altSecurityIdentities servicePrincipalName userPrincipalName

3 Protocol Details

The Remote Certificate Mapping Protocol utilizes the generic pass-through mechanism, as specified in [MS-NRPC] section 3.2.4.1, using Microsoft Unified Security Protocol Provider. The exchanged messages are `SSL_CERT_LOGON_REQ` and `SSL_CERT_LOGON_RESP`. When the account is found, the associated authorization data (for example, group memberships) is encoded as a PAC, as specified in [MS-PAC], and sent back to the Remote Certificate Mapping Protocol client. If no matching account is found, an error is returned to the client, as specified in section 3.5.2.

3.1 Abstract Data Model

The Remote Certificate Mapping Protocol requires that the server have available to it a database or directory of accounts with authorization information and associated name strings that will be used to query the database. The server will issue queries against this database based on strings extracted from the X.509 certificate.

Note that a degenerate, but legal, server could map any certificate to a single set of authorization data. Or, all certificates could map to a small set of authorization data. For example, a web server could have three levels of service (bronze, silver, and gold) managed by three certificate issuers; the Remote Certificate Mapping Protocol server would then merely map the certificates based on the issuer to one of three possible authorization levels and dispense with a full database.

3.2 Timers

There are no timers for the Remote Certificate Mapping Protocol.

3.3 Initialization

There is no initialization that is specific to the Remote Certificate Mapping Protocol.

3.4 Higher-Layer Triggered Events

The Remote Certificate Mapping Protocol message exchange is triggered by a Remote Certificate Mapping Protocol client that requires user authentication via an X.509 certificate. After this authentication takes place, the Remote Certificate Mapping Protocol client sends the `SSL_CERT_LOGON_REQ` message to the Remote Certificate Mapping Protocol server to obtain authorization information.

3.5 Processing Events and Sequencing Rules

The Remote Certificate Mapping Protocol in itself is a stateless protocol with request/response semantics. The general model is:

- The Remote Certificate Mapping Protocol client **MUST** determine the validity of the certificate by whatever means appropriate to the Remote Certificate Mapping Protocol client when the Remote Certificate Mapping Protocol is used to obtain a principal's authorization information on the basis of which access control is performed. The Remote Certificate Mapping Protocol server has three mechanisms, as specified in sections 3.5.1, 3.5.2, and 3.5.3, for determining the authorization information.
- Upon receiving the `SSL_CERT_LOGON_REQ` message, if the Remote Certificate Mapping Protocol server is able to map the user's X.509 certificate to a particular account and authorization information, it **MUST** send an `SSL_CERT_LOGON_RESP` message to the Remote Certificate Mapping Protocol client. Otherwise, it **MUST** return an error status in the Netlogon generic passthrough function, as specified in [MS-NRPC] section 3.2.4.1.

3.5.1 Client Generation of SSL_CERT_LOGON_REQ Message

The client constructs the SSL_CERT_LOGON_REQ message by setting the user's X.509 certificate, the mapping method by which the server looks up the user's account (expressed via Flags as specified in section 2.2.1) and the X.509 certificate issuing authorities (expressed via **PayLoad** as specified in section 2.2.1). The issuing authorities are set in anchor last order. Anchor last order is defined as the leaf certification authority that issued the client's X.509 certificate is first, followed by the next certification authority in the certificate chain, and the next certification authority, and so on. The name of the root certification authority SHOULD be included in the SSL_CERT_LOGON_REQ message when the user's certificate has been directly issued by the root certification authority.

The Remote Certificate Mapping Protocol client request message is packed as a contiguous buffer and the encoded data is sent in the **LogonData** field in the NETLOGON_GENERIC_INFO structure, as specified in [MS-NRPC] section 2.2.1.4.2, via the generic passthrough capability of Netlogon, as specified in [MS-NRPC] section 3.2.4.1. The **PackageName** field in the NETLOGON_GENERIC_INFO structure, as specified in [MS-NRPC], MUST be a RPC_UNICODE_STRING structure with the string value being "Microsoft Unified Security Protocol Provider".

3.5.2 Server Processing of SSL_CERT_LOGON_REQ Message

Upon receipt of the SSL_CERT_LOGON_REQ message at the server, the server decodes the request. The server MUST examine the requested flags from the client for the **REQ_UPN_MAPPING**, **REQ_SUBJECT_MAPPING**, and **REQ_ISSUER_MAPPING** flags. These correspond to the following methods:

- Method 1: Mapping via the **userPrincipalName** attribute. The Remote Certificate Mapping Protocol client requests this mapping scheme from the Remote Certificate Mapping Protocol server by setting the **REQ_UPN_MAPPING** flag in the SSL_CERT_LOGON_REQ message. If this mapping scheme is allowed by the Remote Certificate Mapping Protocol server's local policy, the Remote Certificate Mapping Protocol server looks up the authorization information by using the **subjectAltName** field, as specified in [X509], contained in the X.509 certificate in the request.

The DC SHOULD perform the following based on the type of certificates in the request:

- For certificates that contain the FQDN (dNSName) in the Subject Alternative Extension ([RFC5280] section 4.2.1.6).

The DC prefixes the FQDN with "host/" to form the service principal name (SPN) name form "host/machinename" and searches within the forest directory for an account that contains this SPN in the servicePrincipalName attribute ([MS-ADA3] section 2.253).

- For certificates that contain the UPN in the Subject Alternative Extension ([RFC5280] section 4.2.1.6).

In X.509 certificates, the UPN is encoded in the subject alternative name extension with object identifier (OID) 1.3.6.1.4.1.311.20.2.3. The character encoding is in UTF8 format if the characters are not U.S. ASCII characters. Details are specified in Appendix C of [RFC4556].

The DC searches within the forest directory for an account containing the UPN in the userPrincipalName attribute ([MS-ADA3] section 2.349).

If successful, the Remote Certificate Mapping Protocol RCMP server constructs a PAC [MS-PAC], containing the authorization information. For more information about the initial population of the PAC structures, see the sections under [MS-KILE] section 3.3.5.6.4.

- Method 2: Mapping via the certificate's subject and issuer distinguished names (DNs). The Remote Certificate Mapping Protocol client requests this mapping scheme from the Remote Certificate Mapping Protocol server, by setting the **REQ_SUBJECT_MAPPING** flag in the SSL_CERT_LOGON_REQ message. If this mapping scheme is allowed by the Remote Certificate

Mapping Protocol server's local policy, the Remote Certificate Mapping Protocol server looks up the authorization information by using the subject name and issuer name contained in the X.509 certificate in the request. The strings SHOULD<2> match. If the match is successful, the Remote Certificate Mapping Protocol server constructs a PAC [MS-PAC], containing the authorization information. For more information about the initial population of the PAC structures, see the sections under [MS-KILE] section 3.3.5.6.4.<3>

- Method 3: Mapping via the certificate's issuer DN. The Remote Certificate Mapping Protocol client requests this mapping scheme from the Remote Certificate Mapping Protocol server, by setting the **REQ_ISSUER_MAPPING** flag in the SSL_CERT_LOGON_REQ message. If this mapping scheme is allowed by the Remote Certificate Mapping Protocol server's local policy, the Remote Certificate Mapping Protocol server looks up the account by using the issuer name that is contained in the X.509 certificate in the request. If the additional **REQ_ISSUER_CHAIN_MAPPING** flag is set, the other issuer names from the SSL_CERT_LOGON_REQ message are also used for the search. Each name from the chain of issuers need to be used as the lookup key until a match is found, in the order from the SSL_CERT_LOGON_REQ message. If successful, the Remote Certificate Mapping Protocol server constructs a PAC [MS-PAC], containing the authorization information. For more information about the initial population of the PAC structures, see the sections under [MS-KILE] section 3.3.5.6.4.<4>
- The server SHOULD try these methods in order as listed in the previous methods; a client MUST NOT rely on the processing order. If none of the methods specified as acceptable by the client can determine the appropriate account to use, the mapping request cannot be satisfied. In this event, there is no SSL_CERT_LOGON_RESP message constructed, and the Netlogon generic passthrough method, as specified in [MS-NRPC] section 3.2.4.1, MUST return error code STATUS_LOGON_FAILURE (0xC000006D), as specified in [MS-ERREF], indicating this failure condition. There is no specific error frame or status code in the SSL_CERT_LOGON_RESP message.

If none of the requested methods are successful, the server does not generate an SSL_CERT_LOGON_RESP message, and instead only returns the error code STATUS_LOGON_FAILURE (0xC000006D) to the client via the return code of the Netlogon generic pass-through, as specified in [MS-NRPC] section 3.2.4.1.

3.5.3 Server Generation of the SSL_CERT_LOGON_RESP Message

The SSL_CERT_LOGON_RESP message is constructed by the server in the event that the certificate was associated successfully with an account, and authorization information can be retrieved. The Remote Certificate Mapping Protocol server constructs a PAC, as specified in [MS-PAC], containing the authorization information. Also, if the Remote Certificate Mapping Protocol server is not authoritative over the user's account, it uses Remote Certificate Mapping Protocol to contact the Remote Certificate Mapping Protocol server that is authoritative, and asks it to build the PAC. The response message supplies the name of the domain that contained the account used as the source of the authorization information.

The response, SSL_CERT_LOGON_RESP (section 2.2.2), is packed as a contiguous buffer and the encoded data is sent in the **LogonData** field in the NETLOGON_GENERIC_INFO structure, as specified in [MS-NRPC] section 2.2.1.4.2.

3.6 Timer Events

There are no timer events for the Remote Certificate Mapping Protocol. All timer events are associated with the Netlogon Remote Protocol specified in [MS-NRPC], which serves as the transport for Remote Certificate Mapping Protocol messages.

3.7 Other Local Events

There are no other local events that affect the operation of this protocol.

4 Protocol Examples

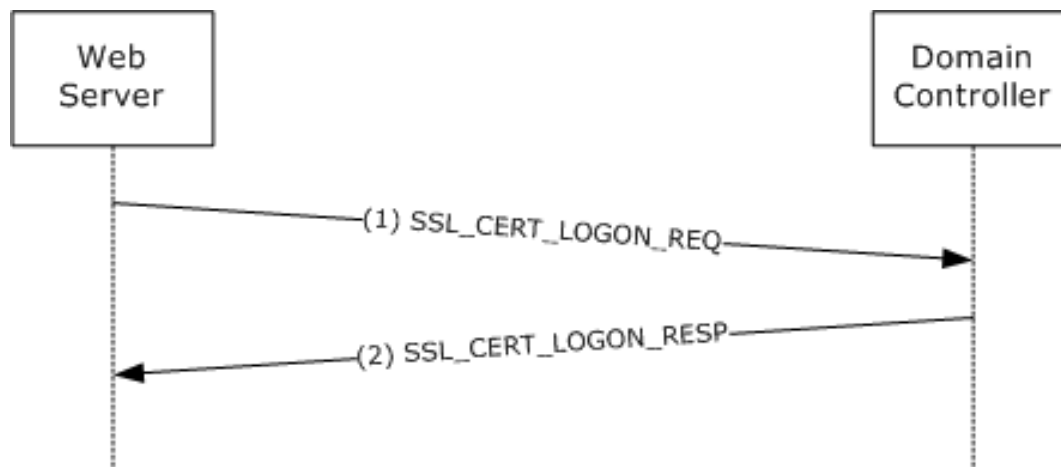

Figure 2: Obtaining a PAC that corresponds to an X.509 certificate

1. A web server requires clients to authenticate via an X.509 certificate. During the Transport Layer Security (TLS) handshake, the client sends the user's X.509 certificate to the server and proves knowledge of the corresponding private key. On completing the handshake, the server side of the TLS implementation builds the `SSL_CERT_LOGON_REQ` message (which contains the user's X.509 certificate) and sends it to the Remote Certificate Mapping Protocol server, in this example, located on a domain controller.
2. The Remote Certificate Mapping Protocol server on the domain controller parses the incoming request and uses the X.509 certificate attributes to look up the user's account in Active Directory. On a successful lookup, the domain controller generates the `SSL_CERT_LOGON_RESP` message, which includes the user's PAC, as specified in [MS-PAC], and sends the message back via the protocol described in [MS-NRPC]. On receiving this message, the server will generate an access token ([MS-DTYP] section 2.5.2) for the client, which it can then use to access resources on the user's behalf.

5 Security

5.1 Security Considerations for Implementers

The Remote Certificate Mapping Protocol enables a user with an X.509 certificate and corresponding private key to gain access to resources based on group information associated with a given Active Directory account. Prior to performing the Remote Certificate Mapping Protocol, the Remote Certificate Mapping Protocol client has to first authenticate the user using the X.509 certificate because the authorization information returned by the Remote Certificate Mapping Protocol server enables the user to gain access to various resources.

The Remote Certificate Mapping Protocol itself does not have any built-in security mechanisms to provide authentication and assure the confidentiality and integrity of the Remote Certificate Mapping Protocol client/Remote Certificate Mapping Protocol server message exchange. Instead, it relies on security mechanisms, as specified in [MS-RPCE], used to protect Netlogon remote procedure call (RPC), as specified in [MS-NRPC], that transport Remote Certificate Mapping Protocol request/response messages.

5.2 Index of Security Parameters

There are no security parameters for the Remote Certificate Mapping Protocol. All associated security parameters are described in [MS-NRPC], which provides all security for Remote Certificate Mapping Protocol messages.

6 (Updated Section) Appendix A: Product Behavior

The information in this specification is applicable to the following Microsoft products or supplemental software. References to product versions include updates to those products.

- Windows NT operating system
- Windows 2000 operating system
- Windows XP operating system
- Windows Server 2003 operating system
- Windows Vista operating system
- Windows Server 2008 operating system
- Windows 7 operating system
- Windows Server 2008 R2 operating system
- Windows 8 operating system
- Windows Server 2012 operating system
- Windows 8.1 operating system
- Windows Server 2012 R2 operating system
- Windows 10 operating system
- Windows Server 2016 operating system
- Windows Server operating system
- **Windows Server 2019 operating system**

Exceptions, if any, are noted in this section. If an update version, service pack or Knowledge Base (KB) number appears with a product name, the behavior changed in that update. The new behavior also applies to subsequent updates unless otherwise specified. If a product edition appears with the product version, behavior is different in that product edition.

Unless otherwise specified, any statement of optional behavior in this specification that is prescribed using the terms "SHOULD" or "SHOULD NOT" implies product behavior in accordance with the SHOULD or SHOULD NOT prescription. Unless otherwise specified, the term "MAY" implies that the product does not follow the prescription.

<1> Section 1.5: Except for Windows NT, which predates Active Directory, Windows uses Active Directory as the database for the authorization. Active Directory uses the distinguished name (DN) of the security principal object and the **userPrincipalName** and **altSecurityIdentities** attributes on the security principal objects for establishing the relationship between the certificates and the authorization information, as specified in [MS-ADTS].

<2> Section 3.5.2: To match strings in Windows, the GetWindowsSortKey algorithm ([MS-UCODEREF] section 3.1.5.2.4) is used with the following flags: **NORM_IGNORECASE**, **NORM_IGNOREKANATYPE**, **NORM_IGNORENONSPACE** and **NORM_IGNOREWIDTH**; then the CompareSortKey algorithm ([MS-UCODEREF] section 3.1.5.2.2) is used to compare strings.

<3> Section 3.5.2: Except for Windows NT, Windows domain controllers extract the issuer DN and the subject DN from the X.509 certificate, and constructs the following string: "<I>[value of issuer]<S>[value of the subject DN]". The resulting string is evaluated against the

altSecurityIdentities attribute of all user and machine account objects, and the scope of this evaluation is the entire forest. The altSecurityIdentities attribute is a multiple-value attribute.

<4> Section 3.5.2: Except for Windows NT, Windows domain controllers extract the issuer DN from the X.509 certificate, and construct the following string: "<I>[value of issuer]". The resulting string is evaluated against the altSecurityIdentities attribute of all user and machine account objects, and the scope of this evaluation is the entire forest. Note that the altSecurityIdentities attribute is a multiple-value attribute.

7 Change Tracking

This section identifies changes that were made to this document since the last release. Changes are classified as Major, Minor, or None.

The revision class **Major** means that the technical content in the document was significantly revised. Major changes affect protocol interoperability or implementation. Examples of major changes are:

- A document revision that incorporates changes to interoperability requirements.
- A document revision that captures changes to protocol functionality.

The revision class **Minor** means that the meaning of the technical content was clarified. Minor changes do not affect protocol interoperability or implementation. Examples of minor changes are updates to clarify ambiguity at the sentence, paragraph, or table level.

The revision class **None** means that no new technical changes were introduced. Minor editorial and formatting changes may have been made, but the relevant technical content is identical to the last released version.

The changes made to this document are listed in the following table. For more information, please contact dochelp@microsoft.com.

Section	Description	Revision class
